CHAPTER

ONE

INTRODUCTION

open62541 (http://open62541.org) is an open source and free implementation of OPC UA (OPC Unified Architecture) written in the common subset of the C99 and C++98 languages. The library is usable with all major compilers and provides the necessary tools to implement dedicated OPC UA clients and servers, or to integrate OPC UA-based communication into existing applications. open62541 library is platform independent. All platform-specific functionality is implemented via exchangeable plugins. Plugin implementations are provided for the major operating systems.

open62541 is licensed under the Mozilla Public License v2.0 (MPLv2). This allows the open62541 library to be combined and distributed with any proprietary software. Only changes to the open62541 library itself need to be licensed under the MPLv2 when copied and distributed. The plugins, as well as the server and client examples are in the public domain (CC0 license). They can be reused under any license and changes do not have to be published.

The sample server (server_ctt) built using open62541 v1.0 is in conformance with the 'Micro Embedded Device Server' Profile of OPC Foundation supporting OPC UA client/server communication, subscriptions, method calls and security (encryption) with the security policies 'Basic128Rsa15', 'Basic256' and 'Basic256Sha256' and the facets 'method server' and 'node management'. See https://open62541.org/certified-sdk for more details.

1.1 OPC Unified Architecture

OPC UA is a protocol for industrial communication and has been standardized in the IEC 62541 series. At its core, OPC UA defines

- an asynchronous *protocol* (built upon TCP, HTTP or SOAP) that defines the exchange of messages via sessions, (on top of) secure communication channels, (on top of) raw connections,
- a type system for protocol messages with a binary and XML-based encoding scheme,
- a meta-model for information modeling, that combines object-orientation with semantic triplerelations, and
- a set of 37 standard *services* to interact with server-side information models. The signature of each service is defined as a request and response message in the protocol type system.

The standard itself can be purchased from IEC or downloaded for free on the website of the OPC Foundation at https://opcfoundation.org/ (you need to register with a valid email).

The OPC Foundation drives the continuous improvement of the standard and the development of companion specifications. Companion specifications translate established concepts and reusable components from an application domain into OPC UA. They are created jointly with an established

industry council or standardization body from the application domain. Furthermore, the OPC Foundation organizes events for the dissemination of the standard and provides the infrastructure and tools for compliance certification.

1.2 open62541 Features

open62541 implements the OPC UA binary protocol stack as well as a client and server SDK. It currently supports the Micro Embedded Device Server Profile plus some additional features. Server binaries can be well under 100kb in size, depending on the contained information model.

- · Communication Stack
 - OPC UA binary protocol
 - Chunking (splitting of large messages)
 - Exchangeable network layer (plugin) for using custom networking APIs (e.g. on embedded targets)
 - Encrypted communication
 - Asynchronous service requests in the client
- · Information model
 - Support for all OPC UA node types (including method nodes)
 - Support for adding and removing nodes and references also at runtime.
 - Support for inheritance and instantiation of object- and variable-types (custom constructor/destructor, instantiation of child nodes)
 - Access control for individual nodes
- Subscriptions
 - Support for subscriptions/monitoreditems for data change notifications
 - Very low resource consumption for each monitored value (event-based server architecture)
- Code-Generation
 - Support for generating data types from standard XML definitions
 - Support for generating server-side information models (nodesets) from standard XML definitions

Features on the roadmap for the 0.3 release series but missing in the initial v0.3 release are:

- Encrypted communication in the client
- Events (notifications emitted by objects, data change notifications are implemented)
- Event-loop (background tasks) in the client

1.3 Getting Help

For discussion and help besides this documentation, you can reach the open62541 community via

- the mailing list
- our IRC channel
- the bugtracker

1.4 Contributing

As an open source project, we invite new contributors to help improve open62541. Issue reports, bugfixes and new features are very welcome. The following are good starting points for new contributors:

- Report bugs
- Improve the documentation
- Work on issues marked as good first issue

CHAPTER

TWO

CORE CONCEPTS OF OPC UA

In one sentence, OPC UA (ISO 62541) defines a framework for object-oriented information models (typically representing a physical device) that live in an OPC UA server and a protocol with which a client can interact with the information model over the network (read and write variables, call methods, instantiate and delete objects, subscribe to change notifications, and so on).

This Section introduces the core concepts of OPC UA. For the full specification see the OPC UA standard at https://reference.opcfoundation.org/.

2.1 Protocol

We focus on the TCP-based binary protocol since it is by far the most common transport layer for OPC UA. The general concepts also translate to HTTP and SOAP-based communication defined in the standard. Communication in OPC UA is best understood by starting with the following key principles:

Request / Response

All communication is based on the Request/Response pattern. Only clients can send a request to a server. And servers can only send responses to a matching request. Often the server is hosted close to a (physical) device, such as a sensor or a machine tool.

Asynchronous Responses

A server does not have to immediately respond to requests and responses may be sent in a different order. This keeps the server responsive when it takes time until a specific request has been processed (e.g. a method call or when reading from a sensor with delay). Subscriptions (push-notifications) are implemented via special requests where the response is delayed until a notification is published.

Note: *OPC UA PubSub* (Part 14 of the standard) is an extension for the integration of many-to-many communication with OPC UA. PubSub does not use the client-server protocol. Rather, OPC UA PubSub integrates with either existing broker-based protocols such as MQTT, UDP-multicast or Ethernet-based communication. Typically an OPC UA server (accessed via the client-server protocol) is used to configured PubSub communication.

Note that the client-server protocol also supports Subscriptions for one-to-one communication and does not depend on PubSub for this feature.

A client-server connection for the OPC UA binary protocol consists of three nested levels: The stateful TCP connection, a SecureChannel and the Session. For full details, see Part 6 of the OPC UA standard.

TCP Connection

The TCP connection is opened to the corresponding hostname and port with an initial hand-shake of HEL/ACK messages. The handshake establishes the basic settings of the connection, such as the maximum message length. The *Reverse Connect* extension of OPC UA allows the server to initiate the underlying TCP connection.

SecureChannel

SecureChannels are created on top of the raw TCP connection. A SecureChannel is established with an *OpenSecureChannel* request and response message pair. **Attention!** Even though a SecureChannel is mandatory, encryption might still be disabled. The *SecurityMode* of a SecureChannel can be either None, Sign, or SignAndEncrypt. As of version 0.2 of open62541, message signing and encryption is still under ongoing development.

With message signing or encryption enabled, the *OpenSecureChannel* messages are encrypted using an asymmetric encryption algorithm (public-key cryptography)¹. As part of the *OpenSecureChannel* messages, client and server establish a common secret over an initially unsecure channel. For subsequent messages, the common secret is used for symmetric encryption, which has the advantage of being much faster.

Different SecurityPolicies – defined in part 7 of the OPC UA standard – specify the algorithms for asymmetric and symmetric encryption, encryption key lengths, hash functions for message signing, and so on. Example SecurityPolicies are None for transmission of cleartext and Basic256Sha256 which mandates a variant of RSA with SHA256 certificate hashing for asymmetric encryption and AES256 for symmetric encryption.

The possible SecurityPolicies of a server are described with a list of *Endpoints*. An endpoint jointly defines the SecurityMode, SecurityPolicy and means for authenticating a session (discussed in the next section) in order to connect to a certain server. The *GetEndpoints* service returns a list of available endpoints. This service can usually be invoked without a session and from an unencrypted SecureChannel. This allows clients to first discover available endpoints and then use an appropriate SecurityPolicy that might be required to open a session.

Session

Sessions are created on top of a SecureChannel. This ensures that users may authenticate without sending their credentials, such as username and password, in cleartext. Currently defined authentication mechanisms are anonymous login, username/password, Kerberos and x509 certificates. The latter requires that the request message is accompanied by a signature to prove that the sender is in possession of the private key with which the certificate was created.

There are two message exchanges required to establish a session: *CreateSession* and *Acticate-Session*. The ActivateSession service can be used to switch an existing session to a different SecureChannel. This is important, for example when the connection broke down and the existing session is reused with a new SecureChannel.

¹ This entails that the client and server exchange so-called public keys. The public keys might come with a certificate from a key-signing authority or be verified against an external key repository. But we will not discuss certificate management in detail in this section.

2.1.1 Structure of a protocol message

Consider the example OPC UA binary conversation in Figure Fig. 2.1, recorded and displayed with Wireshark.

Fig. 2.1: OPC UA conversation displayed in Wireshark

The top part of the Wireshark window shows the messages from the conversation in order. The green line contains the applied filter. Here, we want to see the OPC UA protocol messages only. The first messages (from TCP packets 49 to 56) show the client opening an unencrypted SecureChannel and retrieving the server's endpoints. Then, starting with packet 63, a new connection and SecureChannel are created in conformance with one of the endpoints. On top of this SecureChannel, the client can then create and activate a session. The following *ReadRequest* message is selected and covered in more detail in the bottom windows.

The bottom left window shows the structure of the selected *ReadRequest* message. The purpose of the message is invoking the *Read service*. The message is structured into a header and a message body. Note that we do not consider encryption or signing of messages here.

Message Header

As stated before, OPC UA defines an asynchronous protocol. So responses may be out of order. The message header contains some basic information, such as the length of the message, as well as necessary information to relate messages to a SecureChannel and each request to the corresponding response. "Chunking" refers to the splitting and reassembling of messages that are longer than the maximum network packet size.

Message Body

Every OPC UA *service* has a signature in the form of a request and response data structure. These are defined according to the OPC UA protocol *type system*. See especially the *auto-generated type definitions* for the data types corresponding to service requests and responses. The message body begins with the identifier of the following data type. Then, the main payload of the message follows.

The bottom right window shows the binary payload of the selected *ReadRequest* message. The message header is highlighted in light-grey. The message body in blue highlighting shows the encoded *ReadRequest* data structure.

2.2 Information Modelling

Information modelling in OPC UA combines concepts from object-orientation and semantic modelling. At the core, an OPC UA information model is a graph consisting of Nodes and References between them.

Nodes

There are eight possible NodeClasses for Nodes (Variable, VariableType, Object, ObjectType, ReferenceType, DataType, Method, View). The NodeClass defines the attributes a Node can have.

References

References are links between Nodes. References are typed (refer to a ReferenceType) and directed.

The original source for the following information is Part 3 of the OPC UA specification (https://reference.opcfoundation.org/Core/Part3/).

Each Node is identified by a unique (within the server) *Nodeld* and carries different attributes depending on the NodeClass. These attributes can be read (and sometimes also written) via the OPC UA protocol. The protocol further allows the creation and deletion of Nodes and References at runtime. But this is not supported by all servers.

Reference are triples of the form (source-nodeid, referencetype-nodeid, target-nodeid). (The target-nodeid is actually an *ExpandedNodeId* which is a NodeId that can additionally point to a remote server.) An example reference between nodes is a hasTypeDefinition reference between a Variable and its VariableType. Some ReferenceTypes are *hierarchical* and must not form *directed loops*. See the section on *ReferenceTypes* for more details on possible references and their semantics.

The following table (adapted from Part 3 of the specification) shows which attributes are mandatory (M), optional (0) or not defined for each NodeClass. In open62541 all optional attributes are defined with sensible defaults if users do not change them.

Table 2.1: Node attributes for the different NodeClasses

Attribute	DataType	Vari- able	Variable- Type	Ob- ject	Object- Type	Reference Type	Data- Type	Metho	View
Nodeld	Nodeld	М	М	М	М	М	М	М	М
NodeClass	NodeClass	М	М	М	М	М	М	М	М
BrowseName	Qualified- Name	М	М	М	М	М	М	М	М
DisplayName	LocalizedText	М	М	М	М	М	М	М	М
Description	LocalizedText	0	0	0	0	0	0	0	0
WriteMask	UInt32 (Write Masks)	0	0	0	0	0	0	0 M	0
UserWriteMask	UInt32	0	0	0	0	0	0	0	0
IsAbstract	Boolean		М		М	М	М		
Symmetric	Boolean					М			
InverseName	LocalizedText					0			
Contain- sNoLoops	Boolean								М
EventNotifier	Byte (Event- Notifier)			М				М	М
Value	Variant	М	0						
DataType	Nodeld	М	М						
ValueRank	Int32 (ValueR- ank)	М	М					М	
ArrayDimen- sions	[UInt32]	0	0						
AccessLevel	Byte (Access Level Masks)	М						М	
UserAc- cessLevel	Byte	М							
MinimumSam- plingInterval	Double	0							
Historizing	Boolean	М							
Executable	Boolean							М	
UserExe- cutable	Boolean							М	
DataTypeDefi- nition	DataTypeDef- inition						0		

Each attribute is referenced by a numerical Attribute Id.

Some numerical attributes are used as bitfields or come with special semantics. In particular, see the sections on *Access Level Masks*, *Write Masks*, *ValueRank* and *EventNotifier*.

New attributes in the standard that are still unsupported in open62541 are RolePermissions, User-RolePermissions, AccessRestrictions and AccessLevelEx.

2.2.1 VariableNode

Variables store values in a *DataValue* together with metadata for introspection. Most notably, the attributes data type, value rank and array dimensions constrain the possible values the variable can take on.

Variables come in two flavours: properties and datavariables. Properties are related to a parent with a hasProperty reference and may not have child nodes themselves. Datavariables may contain properties (hasProperty) and also datavariables (hasComponents).

All variables are instances of some *VariableTypeNode* in return constraining the possible data type, value rank and array dimensions attributes.

Data Type

The (scalar) data type of the variable is constrained to be of a specific type or one of its children in the type hierarchy. The data type is given as a Nodeld pointing to a *DataTypeNode* in the type hierarchy. See the Section *DataTypeNode* for more details.

If the data type attribute points to UInt32, then the value attribute must be of that exact type since UInt32 does not have children in the type hierarchy. If the data type attribute points Number, then the type of the value attribute may still be UInt32, but also Float or Byte.

Consistency between the data type attribute in the variable and its VariableTypeNode is ensured.

ValueRank

This attribute indicates whether the value attribute of the variable is an array and how many dimensions the array has. It may have the following values:

- n >= 1: the value is an array with the specified number of dimensions
- n = 0: the value is an array with one or more dimensions
- n = -1: the value is a scalar
- n = -2: the value can be a scalar or an array with any number of dimensions
- n = -3: the value can be a scalar or a one dimensional array

Some helper macros for ValueRanks are defined *here*.

The consistency between the value rank attribute of a VariableNode and its *VariableTypeNode* is tested within the server.

Array Dimensions

If the value rank permits the value to be a (multi-dimensional) array, the exact length in each dimensions can be further constrained with this attribute.

- For positive lengths, the variable value must have a dimension length less or equal to the array dimension length defined in the VariableNode.
- The dimension length zero is a wildcard and the actual value may have any length in this dimension. Note that a value (variant) must have array dimensions that are positive (not zero).

Consistency between the array dimensions attribute in the variable and its VariableTypeNode is ensured. However, we consider that an array of length zero (can also be a null-array with undefined length) has implicit array dimensions $[0,0,\ldots]$. These always match the required array dimensions.

2.2.2 VariableTypeNode

VariableTypes are used to provide type definitions for variables. VariableTypes constrain the data type, value rank and array dimensions attributes of variable instances. Furthermore, instantiating from a specific variable type may provide semantic information. For example, an instance from MotorTemperatureVariableType is more meaningful than a float variable instantiated from BaseDataVariable.

2.2.3 ObjectNode

Objects are used to represent systems, system components, real-world objects and software objects. Objects are instances of an *object type* and may contain variables, methods and further objects.

2.2.4 ObjectTypeNode

ObjectTypes provide definitions for Objects. Abstract objects cannot be instantiated. See *Node Lifecy-cle: Constructors, Destructors and Node Contexts* for the use of constructor and destructor callbacks.

2.2.5 ReferenceTypeNode

Each reference between two nodes is typed with a ReferenceType that gives meaning to the relation. The OPC UA standard defines a set of ReferenceTypes as a mandatory part of OPC UA information models.

- Abstract ReferenceTypes cannot be used in actual references and are only used to structure the ReferenceTypes hierarchy
- Symmetric references have the same meaning from the perspective of the source and target node

The figure below shows the hierarchy of the standard ReferenceTypes (arrows indicate a hasSubType relation). Refer to Part 3 of the OPC UA specification for the full semantics of each ReferenceType.

The ReferenceType hierarchy can be extended with user-defined ReferenceTypes. Many Companion Specifications for OPC UA define new ReferenceTypes to be used in their domain of interest.

For the following example of custom ReferenceTypes, we attempt to model the structure of a technical system. For this, we introduce two custom ReferenceTypes. First, the hierarchical contains ReferenceType indicates that a system (represented by an OPC UA object) contains a component (or subsystem). This gives rise to a tree-structure of containment relations. For example, the motor (object) is contained in the car and the crankshaft is contained in the motor. Second, the symmetric connectedTo ReferenceType indicates that two components are connected. For example, the motor's crankshaft is connected to the gear box. Connections are independent of the containment hierarchy and can induce a general graph-structure. Further subtypes of connectedTo could be used to differentiate between physical, electrical and information related connections. A client can then learn the layout of a (physical) system represented in an OPC UA information model based on a common understanding of just two custom reference types.

2.2.6 DataTypeNode

DataTypes represent simple and structured data types. DataTypes may contain arrays. But they always describe the structure of a single instance. In open62541, DataTypeNodes in the information model hierarchy are matched to UA_DataType type descriptions for *Generic Type Handling* via their Nodeld.

Abstract DataTypes (e.g. Number) cannot be the type of actual values. They are used to constrain values to possible child DataTypes (e.g. UInt32).

2.2.7 MethodNode

Methods define callable functions and are invoked using the *Call* service. MethodNodes may have special properties (variable children with a hasProperty reference) with the *QualifiedName* (0, "InputArguments") and (0, "OutputArguments"). The input and output arguments are both described via an array of UA_Argument. While the Call service uses a generic array of *Variant* for input and output, the actual argument values are checked to match the signature of the MethodNode.

Note that the same MethodNode may be referenced from several objects (and object types). For this, the Nodeld of the method *and of the object providing context* is part of a Call request message.

2.2.8 ViewNode

Each View defines a subset of the Nodes in the AddressSpace. Views can be used when browsing an information model to focus on a subset of nodes and references only. ViewNodes can be created and be interacted with. But their use in the *Browse* service is currently unsupported in open62541.

CHAPTER

THREE

BUILDING OPEN62541

3.1 Building the Library

open62541 uses CMake to build the library and binaries. CMake generates a Makefile or a Visual Studio project. This is then used to perform the actual build.

3.1.1 Building with CMake on Ubuntu or Debian

```
sudo apt-get install git build-essential gcc pkg-config cmake python
# enable additional features
sudo apt-get install cmake-curses-gui # for the ccmake graphical interface
sudo apt-get install libmbedtls-dev # for encryption support
sudo apt-get install check libsubunit-dev # for unit tests
sudo apt-get install python-sphinx graphviz # for documentation generation
sudo apt-get install python-sphinx-rtd-theme # documentation style
cd open62541
mkdir build
cd build
cmake ..
make
# select additional features
ccmake ..
make
# build documentation
make doc # html documentation
make doc_pdf # pdf documentation (requires LaTeX)
```

You can install open62541 using the well known *make install* command. This allows you to use prebuilt libraries and headers for your own project. In order to use open62541 as a shared library (.dll or .so) make sure to activate the BUILD_SHARED_LIBS CMake option.

To override the default installation directory use cmake -DCMAKE_INSTALL_PREFIX=/some/path. Based on the SDK Features you selected, as described in *Build Options*, these features will also be included in the installation. Thus we recommend to enable as many non-experimental features as possible for the installed binary.

In your own CMake project you can then include the open62541 library using:

```
# optionally you can also specify a specific version
# e.g. find_package(open62541 1.0.0)
find_package(open62541 REQUIRED COMPONENTS Events FullNamespace)
add_executable(main main.cpp)
target_link_libraries(main open62541::open62541)
```

A full list of enabled features during build time is stored in the CMake Variable open62541_COMPONENTS_ALL

3.1.2 Building with CMake on Windows

Here we explain the build process for Visual Studio (2013 or newer). To build with MinGW, just replace the compiler selection in the call to CMake.

- · Download and install
 - Python 2.7.x (Python 3.x works as well): https://python.org/downloads
 - CMake: http://www.cmake.org/cmake/resources/software.html
 - Microsoft Visual Studio: https://www.visualstudio.com/products/ visual-studio-community-vs
- Download the open62541 sources (using git or as a zipfile from github)
- Open a command shell (cmd) and run

```
cd <path-to>\open62541
mkdir build
cd build
<path-to>\cmake.exe .. -G "Visual Studio 14 2015"
:: You can use use cmake-gui for a graphical user-interface to select features
```

• Then open buildopen62541. sln in Visual Studio 2015 and build as usual

3.1.3 Building on OS X

- · Download and install
 - Xcode: https://itunes.apple.com/us/app/xcode/id497799835?ls=1&mt=12
 - Homebrew: http://brew.sh/
 - Pip (a package manager for Python, may be preinstalled): sudo easy_install pip
- Run the following in a shell

```
brew install cmake
pip install sphinx # for documentation generation
pip install sphinx_rtd_theme # documentation style
brew install graphviz # for graphics in the documentation
brew install check # for unit tests
```

Follow Ubuntu instructions without the apt-get commands as these are taken care of by the above packages.

3.1.4 Building on OpenBSD

The procedure below works on OpenBSD 5.8 with gcc version 4.8.4, cmake version 3.2.3 and Python version 2.7.10.

• Install a recent gcc, python and cmake:

```
pkg_add gcc python cmake
```

Tell the system to actually use the recent gcc (it gets installed as egcc on OpenBSD):

```
export CC=egcc CXX=eg++
```

• Now procede as described for Ubuntu/Debian:

```
cd open62541
mkdir build
cd build
cmake ..
make
```

3.1.5 Building Debian Packages inside Docker Container with CMake on Ubuntu or Debian

Here is an example howto build the library as Debian package inside a Docker container

- · Download and install
 - Docker Engine: https://docs.docker.com/install/linux/docker-ce/debian/
 - docker-deb-builder: https://github.com/tsaarni/docker-deb-builder.git
 - open62541: https://github.com/open62541/open62541.git

Install Docker as described at https://docs.docker.com/install/linux/docker-ce/debian/.

Get the docker-deb-builder utility from github and make Docker images for the needed Debian and/or Ubuntu relases

```
# make and goto local development path (e.g. ~/development)
mkdir ~/development
cd ~/development

# clone docker-deb-builder utility from github and change into builder directory
git clone https://github.com/tsaarni/docker-deb-builder.git
cd docker-deb-builder

# make Docker builder images (e.g. Ubuntu 18.04 and 17.04)
docker build -t docker-deb-builder:18.04 -f Dockerfile-ubuntu-18.04 .
docker build -t docker-deb-builder:17.04 -f Dockerfile-ubuntu-17.04 .
```

Make a local copy of the open62541 git repo and checkout a pack branch

```
# make a local copy of the open62541 git repo (e.g. in the home directory)
# and checkout a pack branch (e.g. pack/1.0)
cd ~
git clone https://github.com/open62541/open62541.git
cd ~/open62541
git checkout pack/1.0
```

Now it's all set to build Debian/Ubuntu open62541 packages

After a successfull build the Debian/Ubuntu packages can be found at ~/development/docker-deb-builder/output

3.1.6 CMake Build Options and Debian Packaging

If the open62541 library will be build as a Debian package using a pack branch (e.g. pack/master or pack/1.0) then altering or adding CMake build options should be done inside the debian/rules file respectively in the debian/rules-template file if working with a development branch (e.g. master or 1.0).

The section in debian/rules where the CMake build options are defined is

This CMake build options will be passed as command line variables to CMake during Debian packaging.

3.2 Build Options

The open62541 project uses CMake to manage the build options, for code generation and to generate build projects for the different systems and IDEs. The tools *ccmake* or *cmake-gui* can be used to graphically set the build options.

Most options can be changed manually in ua_config.h (open62541.h for the single-file release) after the code generation. But usually there is no need to adjust them.

3.2.1 Main Build Options

CMAKE_BUILD_TYPE

- RelWithDebInfo -O2 optimization with debug symbols
- Release -O2 optimization without debug symbols
- Debug -O0 optimization with debug symbols
- MinSizeRel -Os optimization without debug symbols

UA_LOGLEVEL

The SDK logs events of the level defined in UA_LOGLEVEL and above only. The logging event levels are as follows:

- 600: Fatal
- 500: Error
- 400: Warning
- 300: Info
- 200: Debug
- 100: Trace

UA MULTITHREADING

Level of multi-threading support. The supported levels are currently as follows:

- 0-99: Multithreading support disabled.
- >=100: API functions marked with the UA_THREADSAFE-macro are protected internally
 with mutexes. Multiple threads are allowed to call these functions of the SDK at the same
 time without causing race conditions. Furthermore, this level support the handling of
 asynchronous method calls from external worker threads.

3.2.2 Select build artefacts

By default only the main library shared object libopen62541.so (open62541.dll) or static linking archive open62541.a (open62541.lib) is built. Additional artifacts can be specified by the following options:

UA_BUILD_EXAMPLES

Compile example servers and clients from examples/*.c.

UA_BUILD_UNIT_TESTS

Compile unit tests. The tests can be executed with make test. An individual test can be executed with make test ARGS="-R <test_name> -V". The list of available tests can be displayed with make test ARGS="-N".

UA_BUILD_SELFSIGNED_CERTIFICATE

Generate a self-signed certificate for the server (openSSL required)

3.2.3 Detailed SDK Features

UA_ENABLE_SUBSCRIPTIONS

Enable subscriptions

UA_ENABLE_SUBSCRIPTIONS_EVENTS (EXPERIMENTAL)

Enable the use of events for subscriptions. This is a new feature and currently marked as EX-PERIMENTAL.

UA_ENABLE_SUBSCRIPTIONS_ALARMS_CONDITIONS (EXPERIMENTAL)

Enable the use of A&C for subscriptions. This is a new feature build upon events and currently marked as EXPERIMENTAL.

UA ENABLE METHODCALLS

Enable the Method service set

UA_ENABLE_PARSING

Enable parsing human readable formats of builtin data types (Guid, Nodeld, etc.). Utility functions that are not essential to the SDK.

UA_ENABLE_NODEMANAGEMENT

Enable dynamic addition and removal of nodes at runtime

UA_ENABLE_AMALGAMATION

Compile a single-file release into the files open62541.c and open62541.h. Not recommended for installation.

UA ENABLE IMMUTABLE NODES

Nodes in the information model are not edited but copied and replaced. The replacement is done with atomic operations so that the information model is always consistent and can be accessed from an interrupt or parallel thread (depends on the node storage plugin implementation).

UA_ENABLE_COVERAGE

Measure the coverage of unit tests

UA ENABLE DISCOVERY

Enable Discovery Service (LDS)

UA_ENABLE_DISCOVERY_MULTICAST

Enable Discovery Service with multicast support (LDS-ME)

UA_ENABLE_DISCOVERY_SEMAPHORE

Enable Discovery Semaphore support

UA ENABLE ENCRYPTION

Enable encryption support and specify the used encryption backend. The possible options are: - OFF No encryption support. (default) - MBEDTLS Encryption support using mbed TLS - OPENSSL Encryption support using OpenSSL - LIBRESSL EXPERIMENTAL: Encryption support using LibreSSL

UA_ENABLE_ENCRYPTION_TPM2

Enable TPM hardware for encryption. The possible options are:

- OFF No TPM encryption support. (default)
- ON TPM encryption support

UA_NAMESPACE_ZERO

Namespace zero contains the standard-defined nodes. The full namespace zero may not be required for all applications. The selectable options are as follows:

- MINIMAL: A barebones namespace zero that is compatible with most clients. But this
 namespace 0 is so small that it does not pass the CTT (Conformance Testing Tools
 of the OPC Foundation).
- REDUCED: Small namespace zero that passes the CTT.
- FULL: Full namespace zero generated from the official XML definitions.

The advanced build option UA_FILE_NS0 can be used to override the XML file used for namespace zero generation.

Some options are marked as advanced. The advanced options need to be toggled to be visible in the cmake GUIs.

UA ENABLE TYPEDESCRIPTION

Add the type and member names to the UA_DataType structure. Enabled by default.

UA ENABLE STATUSCODE DESCRIPTIONS

Compile the human-readable name of the StatusCodes into the binary. Enabled by default.

UA ENABLE FULL NS0

Use the full NS0 instead of a minimal Namespace 0 nodeset UA_FILE_NS0 is used to specify the file for NS0 generation from namespace0 folder. Default value is Opc.Ua.NodeSet2.xml

3.2.4 PubSub Build Options

UA_ENABLE_PUBSUB

Enable the experimental OPC UA PubSub support. The option will include the PubSub UDP multicast plugin. Disabled by default.

UA_ENABLE_PUBSUB_DELTAFRAMES

The PubSub messages differentiate between keyframe (all published values contained) and deltaframe (only changed values contained) messages. Deltaframe messages creation consumes some additional resources and can be disabled with this flag. Disabled by default.

UA ENABLE PUBSUB_FILE_CONFIG

Enable loading OPC UA PubSub configuration from File/ByteString. Enabling PubSub informationmodel methods also will add a method to the Publish/Subscribe object which allows configuring PubSub at runtime.

UA_ENABLE_PUBSUB_INFORMATIONMODEL

Enable the information model representation of the PubSub configuration. For more details take a look at the following section *PubSub Information Model Representation*. Disabled by default.

UA_ENABLE_PUBSUB_MONITORING

Enable the experimental PubSub monitoring. This feature provides a basic framework to implement monitoring/timeout checks for PubSub components. Initially the MessageReceiveTimeout check of a DataSetReader is provided. It uses the internal server callback implementation. The monitoring backend can be changed by the application to satisfy realtime requirements. Disabled by default.

3.2.5 Debug Build Options

This group contains build options mainly useful for development of the library itself.

UA_DEBUG

Enable assertions and additional definitions not intended for production builds

UA_DEBUG_DUMP_PKGS

Dump every package received by the server as hexdump format

3.2.6 Building a shared library

open62541 is small enough that most users will want to statically link the library into their programs. If a shared library (.dll, .so) is required, this can be enabled in CMake with the BUILD_SHARED_LIBS option. Note that this option modifies the ua_config.h file that is also included in open62541.h for the single-file distribution.

3.2.7 Minimizing the binary size

The size of the generated binary can be reduced considerably by adjusting the build configuration. With open62541, it is possible to configure minimal servers that require less than 100kB of RAM and ROM.

The following options influence the ROM requirements:

First, in CMake, the build type can be set to CMAKE_BUILD_TYPE=MinSizeRel. This sets the compiler flags to minimize the binary size. The build type also strips out debug information. Second, the binary size can be reduced by removing features via the build-flags described above.

Second, setting UA_NAMESPACE_ZERO to MINIMAL reduces the size of the builtin information model. Setting this option can reduce the binary size by half in some cases.

Third, some features might not be needed and can be disabled to reduce the binary footprint. Examples for this are Subscriptions or encrypted communication.

Last, logging messages take up a lot of space in the binary and might not be needed in embedded scenarios. Setting UA_LOGLEVEL to a value above 600 (FATAL) disables all logging. In addition, the feature-flags UA_ENABLE_TYPEDESCRIPTION and UA_ENABLE_STATUSCODE_DESCRIPTIONS add static information to the binary that is only used for human-readable logging and debugging.

The RAM requirements of a server are mostly due to the following settings:

- The size of the information model
- The number of connected clients
- The configured maximum message size that is preallocated

3.3 Prebuilt packages

3.3.1 Debian

Debian packages can be found in our official PPA:

- Daily Builds (based on master branch): https://launchpad.net/~open62541-team/+archive/ ubuntu/daily
- Release Builds (starting with Version 0.4): https://launchpad.net/~open62541-team/+archive/ ubuntu/ppa

Install them with:

```
sudo add-apt-repository ppa:open62541-team/ppa
sudo apt-get update
sudo apt-get install libopen62541-1-dev
```

3.3.2 Arch

Arch packages are available in the AUR:

- Stable Builds: https://aur.archlinux.org/packages/open62541/
- Unstable Builds (current master): https://aur.archlinux.org/packages/open62541-git/
- In order to add custom build options (Build Options), you can set the environment variable OPEN62541_CMAKE_FLAGS

3.3.3 OpenBSD

Starting with OpenBSD 6.7 the ports directory misc/open62541 can build the released version of open62541. Install the binary package from the OpenBSD mirrors:

```
pkg_add open62541
```

3.4 Building the Examples

Make sure that you have installed the shared library as explained in the previous steps. Then the build system should automatically find the includes and the shared library.

```
cp /path-to/examples/tutorial_server_firststeps.c . # copy the example server
gcc -std=c99 -o server tutorial_server_firststeps.c -lopen62541
```

3.5 Building for specific architectures

The open62541 library can be build for many operating systems and embedded systems. This document shows a small excerpt of already tested architectures. Since the stack is only using the C99 standard, there are many more supported architectures.

A full list of implemented architecture support can be found in the arch folder.

3.5.1 Windows, Linux, MacOS

These architectures are supported by default and are automatically chosen by CMake.

Have a look into the previous sections on how to do that.

3.5.2 freeRTOS + LwIP

Credits to @cabralfortiss

This documentation is based on the discussion of the PR https://github.com/open62541/open62541/pull/2511. If you have any doubts, please first check the discussion there.

This documentation assumes that you have a basic example using LwIP and freeRTOS that works fine, and you only want to add an OPC UA task to it.

There are two main ways to build open62541 for freeRTOS + LwIP:

- Select the cross compiler in CMake, set the flags needed for compilation (different for each microcontroller so it can be difficult) and then run make in the folder and the library should be generated. This method can be hard to do because you need to specify the include files and some other configurations.
- Generate the open6254.h and open6254.c files with the freeRTOSLWIP architecture and then put these files in your project in your IDE that you're using for compiling. This is the easiest way of doing it and the documentation only focus on this method.

In CMake, select freertosLWIP using the variable UA_ARCHITECTURE, enable amalgamation using the UA_ENABLE_AMALGAMATION variable and just select the native compilers. Then try to compile as always. The compilation will fail, but the open62541.h and open62541.c will be generated.

NOTE: If you are using the memory allocation functions from freeRTOS (pvPortMalloc and family) you will need also to set the variable UA_ARCH_FREERTOS_USE_OWN_MEMORY_FUNCTIONS to true. Many users had to implement pvPortCalloc and pvPortRealloc.

If using the terminal, the command should look like this

```
mkdir build_freeRTOS
cd build_freeRTOS
cmake -DUA_ARCHITECTURE=freertosLWIP -DUA_ENABLE_AMALGAMATION=ON ../
make
```

Remember, the compilation will fail. That's not a problem, because you need only the generated files (open62541.h and open62541.c) found in the directory where you tried to compile. Import these in your IDE that you're using. There is no standard way of doing the following across all IDEs, but you need to do the following configurations in your project:

- Add the open62541.c file for compilation
- Add the variable UA_ARCHITECTURE_FREERTOSLWIP to the compilation
- Make sure that the open62541.h is in a folder which is included in the compilation.

When compiling LwIP you need a file called lwipopts.h. In this file, you put all the configuration variables. You need to make sure that you have the following configurations there:

```
#define LWIP_COMPAT_SOCKETS 0 // Don't do name define-transformation in networking_
function names.

#define LWIP_SOCKET 1 // Enable Socket API (normally already set)

#define LWIP_DNS 1 // enable the lwip_getaddrinfo function, struct addrinfo and_
more.

#define SO_REUSE 1 // Allows to set the socket as reusable

#define LWIP_TIMEVAL_PRIVATE 0 // This is optional. Set this flag if you get a_
compilation error about redefinition of struct timeval
```

For freeRTOS there's a similar file called FreeRTOSConfig.h. Usually, you should have an example project with this file. The only two variables that are recommended to check are:

```
#define configCHECK_FOR_STACK_OVERFLOW 1
#define configUSE_MALLOC_FAILED_HOOK 1
```

Most problems when running the OPC UA server in freeRTOS + LwIP come from the fact that is usually deployed in embedded systems with a limited amount of memory, so these definitions will allow checking if there was a memory problem (will save a lot of effort looking for hidden problems).

Now, you need to add the task that will start the OPC UA server.

```
static void opcua_thread(void *arg){
       //The default 64KB of memory for sending and receicing buffer caused_
→problems to many users. With the code below, they are reduced to ~16KB
       UA_UInt16 portNumber = 4840;
       UA_Server* mUaServer = UA_Server_new();
       UA_ServerConfig *uaServerConfig = UA_Server_getConfig(mUaServer);
       UA_ServerConfig_setMinimal(uaServerConfig, portNumber, 0, sendBufferSize,_
→recvBufferSize);
       //VERY IMPORTANT: Set the hostname with your IP before starting the server
       UA_ServerConfig_setCustomHostname(uaServerConfig, UA_STRING("192.168.0.102
→"));
       //The rest is the same as the example
       UA_Boolean running = true;
       // add a variable node to the adresspace
       UA_VariableAttributes attr = UA_VariableAttributes_default;
```

```
UA_Int32 myInteger = 42;
       UA_Variant_setScalarCopy(&attr.value, &myInteger, &UA_TYPES[UA_TYPES_
→INT32]);
        attr.description = UA_LOCALIZEDTEXT_ALLOC("en-US", "the answer");
        attr.displayName = UA_LOCALIZEDTEXT_ALLOC("en-US", "the answer");
       UA_NodeId myIntegerNodeId = UA_NODEID_STRING_ALLOC(1, "the.answer");
       UA_QualifiedName myIntegerName = UA_QUALIFIEDNAME_ALLOC(1, "the answer");
       UA_NodeId parentNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER);
       UA_NodeId parentReferenceNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES);
       UA_Server_addVariableNode(mUaServer, myIntegerNodeId, parentNodeId,
→parentReferenceNodeId, myIntegerName,
                                                                UA_NODEID_NULL,_
→attr, NULL, NULL);
       /* allocations on the heap need to be freed */
       UA_VariableAttributes_clear(&attr);
       UA_NodeId_clear(&myIntegerNodeId);
       UA_QualifiedName_clear(&myIntegerName);
       UA_StatusCode retval = UA_Server_run(mUaServer, &running);
       UA_Server_delete(mUaServer);
}
```

In your main function, after you initialize the TCP IP stack and all the hardware, you need to add the task:

And lastly, in the same file (or any actually) add:

```
void vApplicationMallocFailedHook(){
    for(;;){
         vTaskDelay(pdMS_TO_TICKS(1000));
    }
}

void vApplicationStackOverflowHook( TaskHandle_t xTask, char *pcTaskName ){
    for(;;){
         vTaskDelay(pdMS_TO_TICKS(1000));
    }
}
```

And put a breakpoint in each of the vTaskDelay. These functions are called when there's a problem in the heap or the stack. If the program gets here, you have a memory problem.

That's it. Your OPC UA server should run smoothly. If not, as said before, check the discussion in https://github.com/open62541/open62541/pull/2511. If you still have problems, ask there so the dis-

cussion remains centralized.

CHAPTER

FOUR

TUTORIALS

4.1 Working with Data Types

OPC UA defines a type system for values that can be encoded in the protocol messages. This tutorial shows some examples for available data types and their use. See the section on *Data Types* for the full definitions.

4.1.1 Basic Data Handling

This section shows the basic interaction patterns for data types. Make sure to compare with the type definitions in types.h.

```
#include <open62541/plugin/log_stdout.h>
#include <open62541/server.h>
#include <open62541/server_config_default.h>
#include <stdlib.h>
#include <stdio.h>
static void
variables_basic(void) {
    /* Int32 */
    UA_Int32 i = 5;
    UA_Int32 j;
    UA_Int32_copy(&i, &j);
    UA_Int32 *ip = UA_Int32_new();
    UA_Int32_copy(&i, ip);
    UA_Int32_delete(ip);
    /* String */
    UA_String s;
    UA_String_init(&s); /* _init zeroes out the entire memory of the datatype */
    char *test = "test";
    s.length = strlen(test);
    s.data = (UA_Byte*)test;
    UA_String s2;
```

(continued from previous page)

```
UA_String_copy(&s, &s2);
    UA_String_clear(&s2); /* Copying heap-allocated the dynamic content */
    UA_String s3 = UA_STRING("test2");
    UA_String s4 = UA_STRING_ALLOC("test2"); /* Copies the content to the heap */
    UA_Boolean eq = UA_String_equal(&s3, &s4);
    UA_String_clear(&s4);
    if(!eq)
        return:
    /* Structured Type */
   UA_ReadRequest rr;
    UA_init(&rr, &UA_TYPES[UA_TYPES_READREQUEST]); /* Generic method */
    UA_ReadRequest_init(&rr); /* Shorthand for the previous line */
    rr.requestHeader.timestamp = UA_DateTime_now(); /* Members of a structure */
    rr.nodesToRead = (UA_ReadValueId *)UA_Array_new(5, &UA_TYPES[UA_TYPES_
→READVALUEID]);
    rr.nodesToReadSize = 5; /* Array size needs to be made known */
   UA_ReadRequest *rr2 = UA_ReadRequest_new();
   UA_copy(&rr, rr2, &UA_TYPES[UA_TYPES_READREQUEST]);
   UA_ReadRequest_clear(&rr);
   UA_ReadRequest_delete(rr2);
}
```

4.1.2 Nodelds

An OPC UA information model is made up of nodes and references between nodes. Every node has a unique *Nodeld*. Nodelds refer to a namespace with an additional identifier value that can be an integer, a string, a guid or a bytestring.

```
static void
variables_nodeids(void) {
    UA_NodeId id1 = UA_NODEID_NUMERIC(1, 1234);
    id1.namespaceIndex = 3;

    UA_NodeId id2 = UA_NODEID_STRING(1, "testid"); /* the string is static */
    UA_Boolean eq = UA_NodeId_equal(&id1, &id2);
    if(eq)
        return;

    UA_NodeId id3;
    UA_NodeId_copy(&id2, &id3);
    UA_NodeId_clear(&id3);

    UA_NodeId id4 = UA_NODEID_STRING_ALLOC(1, "testid"); /* the string is copied
```

(continued from previous page)

```
UA_NodeId_clear(&id4);
}
```

4.1.3 Variants

The datatype *Variant* belongs to the built-in datatypes of OPC UA and is used as a container type. A variant can hold any other datatype as a scalar (except variant) or as an array. Array variants can additionally denote the dimensionality of the data (e.g. a 2x3 matrix) in an additional integer array.

```
static void
variables_variants(void) {
    /* Set a scalar value */
    UA_Variant v;
    UA_Int32 i = 42;
    UA_Variant_setScalar(&v, &i, &UA_TYPES[UA_TYPES_INT32]);
    /* Make a copy */
    UA_Variant v2;
    UA_Variant_copy(&v, &v2);
   UA_Variant_clear(&v2);
    /* Set an array value */
    UA_Variant v3;
    UA_Double d[9] = \{1.0, 2.0, 3.0,
                      4.0, 5.0, 6.0,
                      7.0, 8.0, 9.0};
    UA_Variant_setArrayCopy(&v3, d, 9, &UA_TYPES[UA_TYPES_DOUBLE]);
    /* Set array dimensions */
    v3.arrayDimensions = (UA_UInt32 *)UA_Array_new(2, &UA_TYPES[UA_TYPES_UINT32]);
    v3.arrayDimensionsSize = 2;
    v3.arrayDimensions[0] = 3;
    v3.arrayDimensions[1] = 3;
    UA_Variant_clear(&v3);
}
#ifdef UA_ENABLE_JSON_ENCODING
static void
prettyprint(void) {
    UA_ReadRequest rr;
    UA_ReadRequest_init(&rr);
    UA_ReadValueId rvi[2];
    UA_ReadValueId_init(rvi);
    UA_ReadValueId_init(&rvi[1]);
    rr.nodesToRead = rvi;
    rr.nodesToReadSize = 2;
    UA_String out = UA_STRING_NULL;
```

```
UA_print(&rr, &UA_TYPES[UA_TYPES_READREQUEST], &out);
    printf("%.*s\n", (int)out.length, out.data);
    UA_String_clear(&out);
    UA_ReadResponse resp;
    UA_ReadResponse_init(&resp);
    UA_print(&resp, &UA_TYPES[UA_TYPES_READRESPONSE], &out);
    printf("%.*s\n", (int)out.length, out.data);
    UA_String_clear(&out);
    UA_ReferenceDescription br;
    UA_ReferenceDescription_init(&br);
    br.nodeClass = (UA_NodeClass)5;
    UA_print(&br, &UA_TYPES[UA_TYPES_REFERENCEDESCRIPTION], &out);
    printf("%.*s\n", (int)out.length, out.data);
    UA_String_clear(&out);
    UA_Float\ matrix[4] = \{1.0, 2.0, 3.0, 4.0\};
    UA\_UInt32 matrix\_dims[2] = \{2, 2\};
    UA_DataValue dv;
    UA_DataValue_init(&dv);
    UA_Variant_setArray(&dv.value, &matrix, 4, &UA_TYPES[UA_TYPES_FLOAT]);
    dv.value.arrayDimensions = matrix_dims;
    dv.value.arrayDimensionsSize = 2;
    dv.hasValue = true;
    dv.hasStatus = true;
    dv.hasServerTimestamp = true;
    dv.hasSourcePicoseconds = true;
    UA_print(&dv, &UA_TYPES[UA_TYPES_DATAVALUE], &out);
    printf("%.*s\n", (int)out.length, out.data);
    UA_String_clear(&out);
#endif
```

It follows the main function, making use of the above definitions.

```
int main(void) {
   variables_basic();
   variables_nodeids();
   variables_variants();
```

4.2 Building a Simple Server

This series of tutorial guide you through your first steps with open62541. For compiling the examples, you need a compiler (MS Visual Studio 2015 or newer, GCC, Clang and MinGW32 are all known to be working). The compilation instructions are given for GCC but should be straightforward to adapt.

It will also be very helpful to install an OPC UA Client with a graphical frontend, such as UAExpert by Unified Automation. That will enable you to examine the information model of any OPC UA server.

To get started, downdload the open62541 single-file release from http://open62541.org or generate it according to the *build instructions* with the "amalgamation" option enabled. From now on, we assume you have the open62541.c/.h files in the current folder. Now create a new C source-file called myServer.c with the following content:

```
#include <open62541/server.h>
int main(void) {
    UA_Server *server = UA_Server_new();
    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

This is all that is needed for a simple OPC UA server. With the GCC compiler, the following command produces an executable:

```
$ gcc -std=c99 myServer.c -lopen62541 -o myServer
```

In a MinGW environment, the Winsock library must be added.

```
$ gcc -std=c99 myServer.c -lopen62541 -lws2_32 -o myServer.exe
```

Now start the server (stop with ctrl-c):

```
$ ./myServer
```

You have now compiled and run your first OPC UA server. You can go ahead and browse the information model with client. The server is listening on opc.tcp://localhost:4840.

4.2.1 Server Configuration and Plugins

open62541 provides a flexible framework for building OPC UA servers and clients. The goals is to have a core library that accommodates for all use cases and runs on all platforms. Users can then adjust the library to fit their use case via configuration and by developing (platform-specific) plugins. The core library is based on C99 only and does not even require basic POSIX support. For example, the lowlevel networking code is implemented as an exchangeable plugin. But don't worry. open62541 provides plugin implementations for most platforms and sensible default configurations out-of-the-box.

In the above server code, we simply take the default server configuration and add a single TCP network layer that is listerning on port 4840.

4.2.2 Server Lifecycle

The code in this example shows the three parts for server lifecycle management: Creating a server, running the server, and deleting the server. Creating and deleting a server is trivial once the configuration is set up. The server is started with UA_Server_run. Internally, the server schedules regular tasks. Between the timeouts, the server listens on the network layer for incoming messages.

In order to integrate OPC UA in a single-threaded application with its own mainloop (for example provided by a GUI toolkit), one can alternatively drive the server manually. See the section of the server documentation on *Server Lifecycle* for details.

4.3 Adding Variables to a Server

This tutorial shows how to work with data types and how to add variable nodes to a server. First, we add a new variable to the server. Take a look at the definition of the UA_VariableAttributes structure to see the list of all attributes defined for VariableNodes.

Note that the default settings have the AccessLevel of the variable value as read only. See below for making the variable writable.

```
#include <open62541/plugin/log_stdout.h>
#include <open62541/server.h>
#include <stdio.h>
static void
addVariable(UA_Server *server) {
    /* Define the attribute of the myInteger variable node */
    UA_VariableAttributes attr = UA_VariableAttributes_default;
    UA_Int32 myInteger = 42;
    UA_Variant_setScalar(&attr.value, &myInteger, &UA_TYPES[UA_TYPES_INT32]);
    attr.description = UA_LOCALIZEDTEXT("en-US", "the answer");
    attr.displayName = UA_LOCALIZEDTEXT("en-US", "the answer");
    attr.dataType = UA_TYPES[UA_TYPES_INT32].typeId;
    attr.accessLevel = UA_ACCESSLEVELMASK_READ | UA_ACCESSLEVELMASK_WRITE;
    /* Add the variable node to the information model */
    UA_NodeId myIntegerNodeId = UA_NODEID_STRING(1, "the.answer");
    UA_QualifiedName myIntegerName = UA_QUALIFIEDNAME(1, "the answer");
    UA_NodeId parentNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER);
    UA_NodeId parentReferenceNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES);
    UA_Server_addVariableNode(server, myIntegerNodeId, parentNodeId,
                              parentReferenceNodeId, myIntegerName,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),_
→attr, NULL, NULL);
}
static void
addMatrixVariable(UA_Server *server) {
    UA_VariableAttributes attr = UA_VariableAttributes_default;
    attr.displayName = UA_LOCALIZEDTEXT("en-US", "Double Matrix");
```

```
attr.accessLevel = UA_ACCESSLEVELMASK_READ | UA_ACCESSLEVELMASK_WRITE;
    /* Set the variable value constraints */
    attr.dataType = UA_TYPES[UA_TYPES_DOUBLE].typeId;
    attr.valueRank = UA_VALUERANK_TWO_DIMENSIONS;
    UA\_UInt32 arrayDims[2] = \{2,2\};
    attr.arrayDimensions = arrayDims;
    attr.arrayDimensionsSize = 2;
    /* Set the value. The array dimensions need to be the same for the value. */
    UA_Double zero[4] = \{0.0, 0.0, 0.0, 0.0\};
    UA_Variant_setArray(&attr.value, zero, 4, &UA_TYPES[UA_TYPES_DOUBLE]);
    attr.value.arrayDimensions = arrayDims;
    attr.value.arrayDimensionsSize = 2;
    UA_NodeId myIntegerNodeId = UA_NODEID_STRING(1, "double.matrix");
    UA_QualifiedName myIntegerName = UA_QUALIFIEDNAME(1, "double matrix");
    UA_NodeId parentNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER);
    UA_NodeId parentReferenceNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES);
    UA_Server_addVariableNode(server, myIntegerNodeId, parentNodeId,
                              parentReferenceNodeId, myIntegerName,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              attr, NULL, NULL);
}
```

Now we change the value with the write service. This uses the same service implementation that can also be reached over the network by an OPC UA client.

```
static void
writeVariable(UA_Server *server) {
    UA_NodeId myIntegerNodeId = UA_NODEID_STRING(1, "the.answer");
    /* Write a different integer value */
    UA_Int32 myInteger = 43;
    UA_Variant myVar;
    UA_Variant_init(&myVar);
    UA_Variant_setScalar(&myVar, &myInteger, &UA_TYPES[UA_TYPES_INT32]);
    UA_Server_writeValue(server, myIntegerNodeId, myVar);
    /* Set the status code of the value to an error code. The function
    * UA_Server_write provides access to the raw service. The above
    * UA_Server_writeValue is syntactic sugar for writing a specific node
    * attribute with the write service. */
    UA_WriteValue wv;
    UA_WriteValue_init(&wv);
    wv.nodeId = myIntegerNodeId;
    wv.attributeId = UA_ATTRIBUTEID_VALUE;
    wv.value.status = UA_STATUSCODE_BADNOTCONNECTED;
    wv.value.hasStatus = true;
```

```
UA_Server_write(server, &wv);

/* Reset the variable to a good statuscode with a value */
   wv.value.hasStatus = false;
   wv.value.value = myVar;
   wv.value.hasValue = true;
   UA_Server_write(server, &wv);
}
```

Note how we initially set the DataType attribute of the variable node to the NodeId of the Int32 data type. This forbids writing values that are not an Int32. The following code shows how this consistency check is performed for every write.

```
static void
writeWrongVariable(UA_Server *server) {
    UA_NodeId myIntegerNodeId = UA_NODEID_STRING(1, "the.answer");

    /* Write a string */
    UA_String myString = UA_STRING("test");
    UA_Variant myVar;
    UA_Variant_init(&myVar);
    UA_Variant_setScalar(&myVar, &myString, &UA_TYPES[UA_TYPES_STRING]);
    UA_StatusCode retval = UA_Server_writeValue(server, myIntegerNodeId, myVar);
    printf("Writing a string returned statuscode %s\n", UA_StatusCode_name(retval));
}
```

It follows the main server code, making use of the above definitions.

```
int main(void) {
    UA_Server *server = UA_Server_new();

    addVariable(server);
    addMatrixVariable(server);
    writeVariable(server);
    writeWrongVariable(server);

    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.4 Connecting a Variable with a Physical Process

In OPC UA-based architectures, servers are typically situated near the source of information. In an industrial context, this translates into servers being near the physical process and clients consuming the data at runtime. In the previous tutorial, we saw how to add variables to an OPC UA information model. This tutorial shows how to connect a variable to runtime information, for example from measurements of a physical process. For simplicity, we take the system clock as the underlying "process".

The following code snippets are each concerned with a different way of updating variable values at runtime. Taken together, the code snippets define a compilable source file.

4.4.1 Updating variables manually

As a starting point, assume that a variable for a value of type *DateTime* has been created in the server with the identifier "ns=1,s=current-time". Assuming that our application gets triggered when a new value arrives from the underlying process, we can just write into the variable.

```
#include <open62541/plugin/log_stdout.h>
#include <open62541/server.h>
static void
updateCurrentTime(UA_Server *server) {
    UA_DateTime now = UA_DateTime_now();
    UA_Variant value;
    UA_Variant_setScalar(&value, &now, &UA_TYPES[UA_TYPES_DATETIME]);
    UA_NodeId currentNodeId = UA_NODEID_STRING(1, "current-time-value-callback");
    UA_Server_writeValue(server, currentNodeId, value);
}
static void
addCurrentTimeVariable(UA_Server *server) {
    UA_DateTime now = 0;
    UA_VariableAttributes attr = UA_VariableAttributes_default;
    attr.displayName = UA_LOCALIZEDTEXT("en-US", "Current time - value callback");
    attr.accessLevel = UA_ACCESSLEVELMASK_READ | UA_ACCESSLEVELMASK_WRITE;
    UA_Variant_setScalar(&attr.value, &now, &UA_TYPES[UA_TYPES_DATETIME]);
    UA_NodeId currentNodeId = UA_NODEID_STRING(1, "current-time-value-callback");
   UA_QualifiedName currentName = UA_QUALIFIEDNAME(1, "current-time-value-callback
→");
    UA_NodeId parentNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER);
    UA_NodeId parentReferenceNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES);
    UA_NodeId variableTypeNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_
→BASEDATAVARIABLETYPE);
    UA_Server_addVariableNode(server, currentNodeId, parentNodeId,
                              parentReferenceNodeId, currentName,
                              variableTypeNodeId, attr, NULL, NULL);
    updateCurrentTime(server);
}
```

4.4.2 Variable Value Callback

When a value changes continuously, such as the system time, updating the value in a tight loop would take up a lot of resources. Value callbacks allow to synchronize a variable value with an external representation. They attach callbacks to the variable that are executed before every read and after every write operation.

```
static void
beforeReadTime(UA_Server *server,
               const UA_NodeId *sessionId, void *sessionContext,
               const UA_NodeId *nodeid, void *nodeContext,
               const UA_NumericRange *range, const UA_DataValue *data) {
    updateCurrentTime(server);
}
static void
afterWriteTime(UA_Server *server,
               const UA_NodeId *sessionId, void *sessionContext,
               const UA_NodeId *nodeId, void *nodeContext,
               const UA_NumericRange *range, const UA_DataValue *data) {
   UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                "The variable was updated");
}
static void
addValueCallbackToCurrentTimeVariable(UA_Server *server) {
    UA_NodeId currentNodeId = UA_NODEID_STRING(1, "current-time-value-callback");
    UA_ValueCallback callback ;
    callback.onRead = beforeReadTime;
    callback.onWrite = afterWriteTime;
    UA_Server_setVariableNode_valueCallback(server, currentNodeId, callback);
}
```

4.4.3 Variable Data Sources

With value callbacks, the value is still stored in the variable node. So-called data sources go one step further. The server redirects every read and write request to a callback function. Upon reading, the callback provides a copy of the current value. Internally, the data source needs to implement its own memory management.

```
return UA_STATUSCODE_GOOD;
}
static UA_StatusCode
writeCurrentTime(UA_Server *server,
                 const UA_NodeId *sessionId, void *sessionContext,
                 const UA_NodeId *nodeId, void *nodeContext,
                 const UA_NumericRange *range, const UA_DataValue *data) {
    UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                "Changing the system time is not implemented");
   return UA_STATUSCODE_BADINTERNALERROR;
}
static void
addCurrentTimeDataSourceVariable(UA_Server *server) {
    UA_VariableAttributes attr = UA_VariableAttributes_default;
    attr.displayName = UA_LOCALIZEDTEXT("en-US", "Current time - data source");
    attr.accessLevel = UA_ACCESSLEVELMASK_READ | UA_ACCESSLEVELMASK_WRITE;
    UA_NodeId currentNodeId = UA_NODEID_STRING(1, "current-time-datasource");
    UA_QualifiedName currentName = UA_QUALIFIEDNAME(1, "current-time-datasource");
    UA_NodeId parentNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER);
    UA_NodeId parentReferenceNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES);
    UA_NodeId variableTypeNodeId = UA_NODEID_NUMERIC(0, UA_NS0ID_
→BASEDATAVARIABLETYPE);
    UA_DataSource timeDataSource;
    timeDataSource.read = readCurrentTime;
    timeDataSource.write = writeCurrentTime;
    UA_Server_addDataSourceVariableNode(server, currentNodeId, parentNodeId,
                                        parentReferenceNodeId, currentName,
                                        variableTypeNodeId, attr,
                                        timeDataSource, NULL, NULL);
}
static UA_DataValue *externalValue;
static void
addCurrentTimeExternalDataSource(UA_Server *server) {
   UA_NodeId currentNodeId = UA_NODEID_STRING(1, "current-time-external-source");
    UA_ValueBackend valueBackend;
    valueBackend.backendType = UA_VALUEBACKENDTYPE_EXTERNAL;
    valueBackend.backend.external.value = &externalValue;
   UA_Server_setVariableNode_valueBackend(server, currentNodeId, valueBackend);
}
```

It follows the main server code, making use of the above definitions.

```
int main(void) {
    UA_Server *server = UA_Server_new();

    addCurrentTimeVariable(server);
    addValueCallbackToCurrentTimeVariable(server);
    addCurrentTimeDataSourceVariable(server);
    addCurrentTimeExternalDataSource(server);

    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.5 Working with Variable Types

Variable types have three functions:

- Constrain the possible data type, value rank and array dimensions of the variables of that type. This allows interface code to be written against the generic type definition, so it is applicable for all instances.
- Provide a sensible default value
- Enable a semantic interpretation of the variable based on its type

In the example of this tutorial, we represent a point in 2D space by an array of double values. The following function adds the corresponding VariableTypeNode to the hierarchy of variable types.

```
#include <open62541/plugin/log_stdout.h>
#include <open62541/server.h>
static UA_NodeId pointTypeId;
static void
addVariableType2DPoint(UA_Server *server) {
    UA_VariableTypeAttributes vtAttr = UA_VariableTypeAttributes_default;
    vtAttr.dataType = UA_TYPES[UA_TYPES_DOUBLE].typeId;
    vtAttr.valueRank = UA_VALUERANK_ONE_DIMENSION;
    UA_UInt32 arrayDims[1] = {2};
    vtAttr.arrayDimensions = arrayDims;
    vtAttr.arrayDimensionsSize = 1;
    vtAttr.displayName = UA_LOCALIZEDTEXT("en-US", "2DPoint Type");
    /* a matching default value is required */
    UA_Double zero[2] = \{0.0, 0.0\};
    UA_Variant_setArray(&vtAttr.value, zero, 2, &UA_TYPES[UA_TYPES_DOUBLE]);
    UA_Server_addVariableTypeNode(server, UA_NODEID_NULL,
                                  UA_NODEID_NUMERIC(0, UA_NS0ID_
→BASEDATAVARIABLETYPE),
```

```
UA_NODEID_NUMERIC(0, UA_NS0ID_HASSUBTYPE),
UA_QUALIFIEDNAME(1, "2DPoint Type"), UA_NODEID_
→NULL,
vtAttr, NULL, &pointTypeId);
}
```

Now the new variable type for *2DPoint* can be referenced during the creation of a new variable. If no value is given, the default from the variable type is copied during instantiation.

```
static UA_NodeId pointVariableId;
static void
addVariable(UA_Server *server) {
    /* Prepare the node attributes */
   UA_VariableAttributes vAttr = UA_VariableAttributes_default;
    vAttr.dataType = UA_TYPES[UA_TYPES_DOUBLE].typeId;
    vAttr.valueRank = UA_VALUERANK_ONE_DIMENSION;
    UA_UInt32 arrayDims[1] = {2};
    vAttr.arrayDimensions = arrayDims;
    vAttr.arrayDimensionsSize = 1;
    vAttr.displayName = UA_LOCALIZEDTEXT("en-US", "2DPoint Variable");
    vAttr.accessLevel = UA_ACCESSLEVELMASK_READ | UA_ACCESSLEVELMASK_WRITE;
    /* vAttr.value is left empty, the server instantiates with the default value */
    /* Add the node */
    UA_Server_addVariableNode(server, UA_NODEID_NULL,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "2DPoint Type"), pointTypeId,
                              vAttr, NULL, &pointVariableId);
}
```

The constraints of the variable type are enforced when creating new variable instances of the type. In the following function, adding a variable of *2DPoint* type with a string value fails because the value does not match the variable type constraints.

```
UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
UA_QUALIFIEDNAME(1, "2DPoint Type (fail)"),
→pointTypeId,
vAttr, NULL, NULL);
}
```

The constraints of the variable type are enforced when writing the datatype, valuerank and arraydimensions attributes of the variable. This, in turn, constrains the value attribute of the variable.

It follows the main server code, making use of the above definitions.

```
int main(void) {
    UA_Server *server = UA_Server_new();
    addVariableType2DPoint(server);
    addVariable(server);
    addVariableFail(server);
    writeVariable(server);
    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.6 Working with Objects and Object Types

4.6.1 Using objects to structure information models

Assume a situation where we want to model a set of pumps and their runtime state in an OPC UA information model. Of course, all pump representations should follow the same basic structure, For example, we might have graphical representation of pumps in a SCADA visualisation that shall be resuable for all pumps.

Following the object-oriented programming paradigm, every pump is represented by an object with the following layout:

The following code manually defines a pump and its member variables. We omit setting constraints on the variable values as this is not the focus of this tutorial and was already covered.

```
static void
manuallyDefinePump(UA_Server *server) {
    UA_NodeId pumpId; /* get the nodeid assigned by the server */
    UA_ObjectAttributes oAttr = UA_ObjectAttributes_default;
    oAttr.displayName = UA_LOCALIZEDTEXT("en-US", "Pump (Manual)");
    UA_Server_addObjectNode(server, UA_NODEID_NULL,
                            UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER),
                            UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES),
                            UA_QUALIFIEDNAME(1, "Pump (Manual)"),
                            UA_NODEID_NUMERIC(0, UA_NS0ID_BASE0BJECTTYPE),
                            oAttr, NULL, &pumpId);
    UA_VariableAttributes mnAttr = UA_VariableAttributes_default;
    UA_String manufacturerName = UA_STRING("Pump King Ltd.");
    UA_Variant_setScalar(&mnAttr.value, &manufacturerName, &UA_TYPES[UA_TYPES_
→STRING]);
    mnAttr.displayName = UA_LOCALIZEDTEXT("en-US", "ManufacturerName");
                                                                    (continues on next page)
```

```
UA_Server_addVariableNode(server, UA_NODEID_NULL, pumpId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "ManufacturerName"),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              mnAttr, NULL, NULL);
    UA_VariableAttributes modelAttr = UA_VariableAttributes_default;
    UA_String modelName = UA_STRING("Mega Pump 3000");
    UA_Variant_setScalar(&modelAttr.value, &modelName, &UA_TYPES[UA_TYPES_STRING]);
    modelAttr.displayName = UA_LOCALIZEDTEXT("en-US", "ModelName");
    UA_Server_addVariableNode(server, UA_NODEID_NULL, pumpId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "ModelName"),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              modelAttr, NULL, NULL);
    UA_VariableAttributes statusAttr = UA_VariableAttributes_default;
    UA_Boolean status = true;
    UA_Variant_setScalar(&statusAttr.value, &status, &UA_TYPES[UA_TYPES_BOOLEAN]);
    statusAttr.displayName = UA_LOCALIZEDTEXT("en-US", "Status");
    UA_Server_addVariableNode(server, UA_NODEID_NULL, pumpId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "Status"),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              statusAttr, NULL, NULL);
    UA_VariableAttributes rpmAttr = UA_VariableAttributes_default;
    UA_Double rpm = 50.0;
    UA_Variant_setScalar(&rpmAttr.value, &rpm, &UA_TYPES[UA_TYPES_DOUBLE]);
    rpmAttr.displayName = UA_LOCALIZEDTEXT("en-US", "MotorRPM");
    UA_Server_addVariableNode(server, UA_NODEID_NULL, pumpId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "MotorRPMs"),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              rpmAttr, NULL, NULL);
}
```

4.6.2 Object types, type hierarchies and instantiation

Building up each object manually requires us to write a lot of code. Furthermore, there is no way for clients to detect that an object represents a pump. (We might use naming conventions or similar to detect pumps. But that's not exactly a clean solution.) Furthermore, we might have more devices than just pumps. And we require all devices to share some common structure. The solution is to define ObjectTypes in a hierarchy with inheritance relations.

Children that are marked mandatory are automatically instantiated together with the parent object. This is indicated by a *hasModellingRule* reference to an object that representes the *mandatory* modelling rule.

```
/* predefined identifier for later use */
UA_NodeId pumpTypeId = {1, UA_NODEIDTYPE_NUMERIC, {1001}};
static void
defineObjectTypes(UA_Server *server) {
    /* Define the object type for "Device" */
    UA_NodeId deviceTypeId; /* get the nodeid assigned by the server */
    UA_ObjectTypeAttributes dtAttr = UA_ObjectTypeAttributes_default;
    dtAttr.displayName = UA_LOCALIZEDTEXT("en-US", "DeviceType");
    UA_Server_addObjectTypeNode(server, UA_NODEID_NULL,
                                UA_NODEID_NUMERIC(0, UA_NS0ID_BASE0BJECTTYPE),
                                UA_NODEID_NUMERIC(0, UA_NS0ID_HASSUBTYPE),
                                UA_QUALIFIEDNAME(1, "DeviceType"), dtAttr,
                                NULL, &deviceTypeId);
    UA_VariableAttributes mnAttr = UA_VariableAttributes_default;
    mnAttr.displayName = UA_LOCALIZEDTEXT("en-US", "ManufacturerName");
    UA_NodeId manufacturerNameId;
                                                                    (continues on next page)
```

```
UA_Server_addVariableNode(server, UA_NODEID_NULL, deviceTypeId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "ManufacturerName"),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              mnAttr, NULL, &manufacturerNameId);
   /* Make the manufacturer name mandatory */
   UA_Server_addReference(server, manufacturerNameId,
                           UA_NODEID_NUMERIC(0, UA_NS0ID_HASMODELLINGRULE),
                           UA_EXPANDEDNODEID_NUMERIC(0, UA_NS0ID_MODELLINGRULE_
→MANDATORY), true);
   UA_VariableAttributes modelAttr = UA_VariableAttributes_default;
   modelAttr.displayName = UA_LOCALIZEDTEXT("en-US", "ModelName");
   UA_Server_addVariableNode(server, UA_NODEID_NULL, deviceTypeId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "ModelName"),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              modelAttr, NULL, NULL);
   /* Define the object type for "Pump" */
   UA_ObjectTypeAttributes ptAttr = UA_ObjectTypeAttributes_default;
   ptAttr.displayName = UA_LOCALIZEDTEXT("en-US", "PumpType");
   UA_Server_addObjectTypeNode(server, pumpTypeId,
                                deviceTypeId, UA_NODEID_NUMERIC(0, UA_NS0ID_
→HASSUBTYPE),
                                UA_QUALIFIEDNAME(1, "PumpType"), ptAttr,
                                NULL, NULL);
   UA_VariableAttributes statusAttr = UA_VariableAttributes_default;
   statusAttr.displayName = UA_LOCALIZEDTEXT("en-US", "Status");
   statusAttr.valueRank = UA_VALUERANK_SCALAR;
   UA_NodeId statusId;
   UA_Server_addVariableNode(server, UA_NODEID_NULL, pumpTypeId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                              UA_QUALIFIEDNAME(1, "Status"),
                              UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
                              statusAttr, NULL, &statusId);
   /* Make the status variable mandatory */
   UA_Server_addReference(server, statusId,
                           UA_NODEID_NUMERIC(0, UA_NS0ID_HASMODELLINGRULE),
                           UA_EXPANDEDNODEID_NUMERIC(0, UA_NS0ID_MODELLINGRULE_
→MANDATORY), true);
   UA_VariableAttributes rpmAttr = UA_VariableAttributes_default;
   rpmAttr.displayName = UA_LOCALIZEDTEXT("en-US", "MotorRPM");
   rpmAttr.valueRank = UA_VALUERANK_SCALAR;
   UA_Server_addVariableNode(server, UA_NODEID_NULL, pumpTypeId,
                              UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
```

```
UA_QUALIFIEDNAME(1, "MotorRPMs"),
UA_NODEID_NUMERIC(0, UA_NS0ID_BASEDATAVARIABLETYPE),
rpmAttr, NULL, NULL);
}
```

Now we add the derived ObjectType for the pump that inherits from the device object type. The resulting object contains all mandatory child variables. These are simply copied over from the object type. The object has a reference of type hasTypeDefinition to the object type, so that clients can detect the type-instance relation at runtime.

Often we want to run a constructor function on a new object. This is especially useful when an object is instantiated at runtime (with the AddNodes service) and the integration with an underlying process cannot be manually defined. In the following constructor example, we simply set the pump status to on.

```
static UA_StatusCode
pumpTypeConstructor(UA_Server *server,
                    const UA_NodeId *sessionId, void *sessionContext,
                    const UA_NodeId *typeId, void *typeContext,
                    const UA_NodeId *nodeId, void **nodeContext) {
    UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND, "New pump created");
    /* Find the NodeId of the status child variable */
    UA_RelativePathElement rpe;
    UA_RelativePathElement_init(&rpe);
    rpe.referenceTypeId = UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT);
    rpe.isInverse = false;
    rpe.includeSubtypes = false;
    rpe.targetName = UA_QUALIFIEDNAME(1, "Status");
    UA_BrowsePath bp;
    UA_BrowsePath_init(&bp);
    bp.startingNode = *nodeId;
    bp.relativePath.elementsSize = 1;
    bp.relativePath.elements = &rpe;
    UA_BrowsePathResult bpr =
```

```
UA_Server_translateBrowsePathToNodeIds(server, &bp);
    if(bpr.statusCode != UA_STATUSCODE_GOOD ||
       bpr.targetsSize < 1)</pre>
        return bpr.statusCode;
    /* Set the status value */
    UA_Boolean status = true;
    UA_Variant value;
    UA_Variant_setScalar(&value, &status, &UA_TYPES[UA_TYPES_BOOLEAN]);
    UA_Server_writeValue(server, bpr.targets[0].targetId.nodeId, value);
    UA_BrowsePathResult_clear(&bpr);
    /* At this point we could replace the node context .. */
    return UA_STATUSCODE_GOOD;
}
static void
addPumpTypeConstructor(UA_Server *server) {
    UA_NodeTypeLifecycle lifecycle;
    lifecycle.constructor = pumpTypeConstructor;
    lifecycle.destructor = NULL;
    UA_Server_setNodeTypeLifecycle(server, pumpTypeId, lifecycle);
}
```

It follows the main server code, making use of the above definitions.

```
int main(void) {
    UA_Server *server = UA_Server_new();

    manuallyDefinePump(server);
    defineObjectTypes(server);
    addPumpObjectInstance(server, "pump2");
    addPumpObjectInstance(server, "pump3");
    addPumpTypeConstructor(server);
    addPumpObjectInstance(server, "pump4");
    addPumpObjectInstance(server, "pump5");

UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.7 Adding Methods to Objects

An object in an OPC UA information model may contain methods similar to objects in a programming language. Methods are represented by a MethodNode. Note that several objects may reference the same MethodNode. When an object type is instantiated, a reference to the method is added instead of copying the MethodNode. Therefore, the identifier of the context object is always explicitly stated when a method is called.

The method callback takes as input a custom data pointer attached to the method node, the identifier of the object from which the method is called, and two arrays for the input and output arguments. The input and output arguments are all of type *Variant*. Each variant may in turn contain a (multi-dimensional) array or scalar of any data type.

Constraints for the method arguments are defined in terms of data type, value rank and array dimension (similar to variable definitions). The argument definitions are stored in child VariableNodes of the MethodNode with the respective BrowseNames (0, "InputArguments") and (0, "OutputArguments").

4.7.1 Example: Hello World Method

The method takes a string scalar and returns a string scalar with "Hello" prepended. The type and length of the input arguments is checked internally by the SDK, so that we don't have to verify the arguments in the callback.

```
#include <open62541/client_config_default.h>
#include <open62541/plugin/log_stdout.h>
#include <open62541/server.h>
static UA_StatusCode
helloWorldMethodCallback(UA_Server *server,
                         const UA_NodeId *sessionId, void *sessionHandle,
                         const UA_NodeId *methodId, void *methodContext,
                         const UA_NodeId *objectId, void *objectContext,
                         size_t inputSize, const UA_Variant *input,
                         size_t outputSize, UA_Variant *output) {
    UA_String *inputStr = (UA_String*)input->data;
    UA_String tmp = UA_STRING_ALLOC("Hello ");
    if(inputStr->length > 0) {
        tmp.data = (UA_Byte *)UA_realloc(tmp.data, tmp.length + inputStr->length);
        memcpy(&tmp.data[tmp.length], inputStr->data, inputStr->length);
        tmp.length += inputStr->length;
    UA_Variant_setScalarCopy(output, &tmp, &UA_TYPES[UA_TYPES_STRING]);
    UA_String_clear(&tmp);
    UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_SERVER, "Hello World was called");
    return UA_STATUSCODE_GOOD;
}
static void
addHelloWorldMethod(UA_Server *server) {
   UA_Argument inputArgument;
```

```
UA_Argument_init(&inputArgument);
    inputArgument.description = UA_LOCALIZEDTEXT("en-US", "A String");
    inputArgument.name = UA_STRING("MyInput");
    inputArgument.dataType = UA_TYPES[UA_TYPES_STRING].typeId;
    inputArgument.valueRank = UA_VALUERANK_SCALAR;
    UA_Argument outputArgument;
    UA_Argument_init(&outputArgument);
    outputArgument.description = UA_LOCALIZEDTEXT("en-US", "A String");
    outputArgument.name = UA_STRING("MyOutput");
    outputArgument.dataType = UA_TYPES[UA_TYPES_STRING].typeId;
    outputArgument.valueRank = UA_VALUERANK_SCALAR;
    UA_MethodAttributes helloAttr = UA_MethodAttributes_default;
    helloAttr.description = UA_LOCALIZEDTEXT("en-US", "Say `Hello World`");
    helloAttr.displayName = UA_LOCALIZEDTEXT("en-US", "Hello World");
    helloAttr.executable = true;
    helloAttr.userExecutable = true;
    UA_Server_addMethodNode(server, UA_NODEID_NUMERIC(1,62541),
                            UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER),
                            UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                            UA_QUALIFIEDNAME(1, "hello world"),
                            helloAttr, &helloWorldMethodCallback,
                            1, &inputArgument, 1, &outputArgument, NULL, NULL);
}
```

4.7.2 Increase Array Values Method

The method takes an array of 5 integers and a scalar as input. It returns a copy of the array with every entry increased by the scalar.

```
UA_Int32 *outputArray = (UA_Int32*)output->data;
    for(size_t i = 0; i < input->arrayLength; i++)
        outputArray[i] = inputArray[i] + delta;
    return UA_STATUSCODE_GOOD;
}
static void
addIncInt32ArrayMethod(UA_Server *server) {
    /* Two input arguments */
    UA_Argument inputArguments[2];
    UA_Argument_init(&inputArguments[0]);
    inputArguments[0].description = UA_LOCALIZEDTEXT("en-US", "int32[5] array");
    inputArguments[0].name = UA_STRING("int32 array");
    inputArguments[0].dataType = UA_TYPES[UA_TYPES_INT32].typeId;
    inputArguments[0].valueRank = UA_VALUERANK_ONE_DIMENSION;
    UA_UInt32 pInputDimension = 5;
    inputArguments[0].arrayDimensionsSize = 1;
    inputArguments[0].arrayDimensions = &pInputDimension;
    UA_Argument_init(&inputArguments[1]);
    inputArguments[1].description = UA_LOCALIZEDTEXT("en-US", "int32 delta");
    inputArguments[1].name = UA_STRING("int32 delta");
    inputArguments[1].dataType = UA_TYPES[UA_TYPES_INT32].typeId;
    inputArguments[1].valueRank = UA_VALUERANK_SCALAR;
    /* One output argument */
    UA_Argument outputArgument;
    UA_Argument_init(&outputArgument);
    outputArgument.description = UA_LOCALIZEDTEXT("en-US", "int32[5] array");
    outputArgument.name = UA_STRING("each entry is incremented by the delta");
    outputArgument.dataType = UA_TYPES[UA_TYPES_INT32].typeId;
    outputArgument.valueRank = UA_VALUERANK_ONE_DIMENSION;
    UA_UInt32 pOutputDimension = 5;
    outputArgument.arrayDimensionsSize = 1;
    outputArgument.arrayDimensions = &pOutputDimension;
    /* Add the method node */
    UA_MethodAttributes incAttr = UA_MethodAttributes_default;
    incAttr.description = UA_LOCALIZEDTEXT("en-US", "IncInt32ArrayValues");
    incAttr.displayName = UA_LOCALIZEDTEXT("en-US", "IncInt32ArrayValues");
    incAttr.executable = true;
    incAttr.userExecutable = true;
    UA_Server_addMethodNode(server, UA_NODEID_STRING(1, "IncInt32ArrayValues"),
                            UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER),
                            UA_NODEID_NUMERIC(0, UA_NS0ID_HASCOMPONENT),
                            UA_QUALIFIEDNAME(1, "IncInt32ArrayValues"),
                            incAttr, &IncInt32ArrayMethodCallback,
                            2, inputArguments, 1, &outputArgument,
```

```
NULL, NULL);

}
```

It follows the main server code, making use of the above definitions.

```
int main(void) {
    UA_Server *server = UA_Server_new();

    addHelloWorldMethod(server);
    addIncInt32ArrayMethod(server);

    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.8 Observing Attributes with Local Monitored Items

A client that is interested in the current value of a variable does not need to regularly poll the variable. Instead, the client can use the Subscription mechanism to be notified about changes.

So-called MonitoredItems define which values (node attributes) and events the client wants to monitor. Under the right conditions, a notification is created and added to the Subscription. The notifications currently in the queue are regularly sent to the client.

The local user can add MonitoredItems as well. Locally, the MonitoredItems do not go via a Subscription and each have an individual callback method and a context pointer.

```
#include <open62541/client_subscriptions.h>
#include <open62541/server.h>
#include <open62541/plugin/log_stdout.h>
static void
dataChangeNotificationCallback(UA_Server *server, UA_UInt32 monitoredItemId,
                               void *monitoredItemContext, const UA_NodeId *nodeId,
                               void *nodeContext, UA_UInt32 attributeId,
                               const UA_DataValue *value) {
    UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND, "Received Notification");
}
static void
addMonitoredItemToCurrentTimeVariable(UA_Server *server) {
    UA_NodeId currentTimeNodeId =
        UA_NODEID_NUMERIC(0, UA_NS0ID_SERVER_SERVERSTATUS_CURRENTTIME);
   UA_MonitoredItemCreateRequest monRequest =
       UA_MonitoredItemCreateRequest_default(currentTimeNodeId);
    monRequest.requestedParameters.samplingInterval = 100.0; /* 100 ms interval */
    UA_Server_createDataChangeMonitoredItem(server, UA_TIMESTAMPSTORETURN_SOURCE,
                                            monRequest, NULL,
```

```
dataChangeNotificationCallback);
}
```

It follows the main server code, making use of the above definitions.

```
int main(void) {
    UA_Server *server = UA_Server_new();

    addMonitoredItemToCurrentTimeVariable(server);

    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.9 Generating events

To make sense of the many things going on in a server, monitoring items can be useful. Though in many cases, data change does not convey enough information to be the optimal solution. Events can be generated at any time, hold a lot of information and can be filtered so the client only receives the specific attributes of interest.

4.9.1 Emitting events by calling methods

The following example will be based on the server method tutorial. We will be creating a method node which generates an event from the server node.

The event we want to generate should be very simple. Since the *BaseEventType* is abstract, we will have to create our own event type. *EventTypes* are saved internally as *ObjectTypes*, so add the type as you would a new *ObjectType*.

4.9.2 Setting up an event

In order to set up the event, we can first use UA_Server_createEvent to give us a node representation of the event. All we need for this is our *EventType*. Once we have our event node, which is saved internally as an *ObjectNode*, we can define the attributes the event has the same way we would define the attributes of an object node. It is not necessary to define the attributes *EventId*, *ReceiveTime*, *SourceNode* or *EventType* since these are set automatically by the server. In this example, we will be setting the fields 'Message' and 'Severity' in addition to *Time* which is needed to make the example UaExpert compliant.

```
static UA_StatusCode
setUpEvent(UA_Server *server, UA_NodeId *outId) {
    UA_StatusCode retval = UA_Server_createEvent(server, eventType, outId);
    if (retval != UA_STATUSCODE_GOOD) {
       UA_LOG_WARNING(UA_Log_Stdout, UA_LOGCATEGORY_SERVER,
                       "createEvent failed. StatusCode %s", UA_StatusCode_
→name(retval));
        return retval;
    }
   /* Set the Event Attributes */
   /* Setting the Time is required or else the event will not show up in UAExpert!_
    UA_DateTime eventTime = UA_DateTime_now();
   UA_Server_writeObjectProperty_scalar(server, *outId, UA_QUALIFIEDNAME(0, "Time
→"),
                                         &eventTime, &UA_TYPES[UA_TYPES_DATETIME]);
   UA_UInt16 eventSeverity = 100;
    UA_Server_writeObjectProperty_scalar(server, *outId, UA_QUALIFIEDNAME(0,
→"Severity"),
                                         &eventSeverity, &UA_TYPES[UA_TYPES_
→UINT16]);
    UA_LocalizedText eventMessage = UA_LOCALIZEDTEXT("en-US", "An event has been_
→generated.");
    UA_Server_writeObjectProperty_scalar(server, *outId, UA_QUALIFIEDNAME(0,
→"Message"),
                                         &eventMessage, &UA_TYPES[UA_TYPES_
→LOCALIZEDTEXT]);
    UA_String eventSourceName = UA_STRING("Server");
    UA_Server_writeObjectProperty_scalar(server, *outId, UA_QUALIFIEDNAME(0,
→ "SourceName"),
                                         &eventSourceName, &UA_TYPES[UA_TYPES_
→STRING]);
    return UA_STATUSCODE_GOOD;
}
```

4.9.3 Triggering an event

First a node representing an event is generated using setUpEvent. Once our event is good to go, we specify a node which emits the event - in this case the server node. We can use UA_Server_triggerEvent to trigger our event onto said node. Passing NULL as the second-last argument means we will not receive the *EventId*. The last boolean argument states whether the node should be deleted.

```
static UA_StatusCode
generateEventMethodCallback(UA_Server *server,
                         const UA_NodeId *sessionId, void *sessionHandle,
                         const UA_NodeId *methodId, void *methodContext,
                         const UA_NodeId *objectId, void *objectContext,
                         size_t inputSize, const UA_Variant *input,
                         size_t outputSize, UA_Variant *output) {
    UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND, "Creating event");
    /* set up event */
    UA_NodeId eventNodeId;
    UA_StatusCode retval = setUpEvent(server, &eventNodeId);
    if(retval != UA_STATUSCODE_GOOD) {
        UA_LOG_WARNING(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                       "Creating event failed. StatusCode %s", UA_StatusCode_
→name(retval));
        return retval;
    }
    retval = UA_Server_triggerEvent(server, eventNodeId,
                                    UA_NODEID_NUMERIC(0, UA_NS0ID_SERVER),
                                    NULL, UA_TRUE);
    if(retval != UA_STATUSCODE_GOOD)
        UA_LOG_WARNING(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                       "Triggering event failed. StatusCode %s", UA_StatusCode_
→name(retval));
    return retval;
}
```

Now, all that is left to do is to create a method node which uses our callback. We do not require any input and as output we will be using the *EventId* we receive from triggerEvent. The *EventId* is generated by the server internally and is a random unique ID which identifies that specific event.

This method node will be added to a basic server setup.

```
static void
addGenerateEventMethod(UA_Server *server) {
    UA_MethodAttributes generateAttr = UA_MethodAttributes_default;
    generateAttr.description = UA_LOCALIZEDTEXT("en-US","Generate an event.");
    generateAttr.displayName = UA_LOCALIZEDTEXT("en-US","Generate Event");
    generateAttr.executable = true;
    (continues on next page)
```

It follows the main server code, making use of the above definitions.

```
int main(void) {
    UA_Server *server = UA_Server_new();

    addNewEventType(server);
    addGenerateEventMethod(server);

    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.10 Using Alarms and Conditions Server

Besides the usage of monitored items and events to observe the changes in the server, it is also important to make use of the Alarms and Conditions Server Model. Alarms are events which are triggered automatically by the server dependent on internal server logic or user specific logic when the states of server components change. The state of a component is represented through a condition. So the values of all the condition children (Fields) are the actual state of the component.

4.10.1 Trigger Alarm events by changing States

The following example will be based on the server events tutorial. Please make sure to understand the principle of normal events before proceeding with this example!

```
UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES),
                                      UA_QUALIFIEDNAME(0, "ConditionSourceObject"),
                                      UA_NODEID_NUMERIC(0, UA_NS0ID_BASE0BJECTTYPE),
                                      object_attr, NULL, &conditionSource);
    if(retval != UA_STATUSCODE_GOOD) {
       UA_LOG_ERROR(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                     "Creating Condition Source failed. StatusCode %s",
                     UA_StatusCode_name(retval));
    }
   /* ConditionSource should be EventNotifier of another Object (usually the
    * Server Object). If this Reference is not created by user then the A&C
    * Server will create "HasEventSource" reference to the Server Object
    * automatically when the condition is created*/
    retval = UA_Server_addReference(server, UA_NODEID_NUMERIC(0, UA_NS0ID_SERVER),
                                     UA_NODEID_NUMERIC(0, UA_NS0ID_HASNOTIFIER),

    return retval;
}
/* Severity can change internally also when the condition disabled and
* retain is false. However, in this case no events will be generated. */
addVariable_2_changeSeverityOfCondition_2(server, &variable_2);
callback.onWrite = afterWriteCallbackVariable_2;
retval = UA_Server_setVariableNode_valueCallback(server, variable_2, callback);
if(retval != UA_STATUSCODE_GOOD) {
   UA_LOG_ERROR(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                 "Setting variable 2 Callback failed. StatusCode %s",
                 UA_StatusCode_name(retval));
    return retval;
}
addVariable_3_returnCondition_1_toNormalState(server, &variable_3);
callback.onWrite = afterWriteCallbackVariable_3;
retval = UA_Server_setVariableNode_valueCallback(server, variable_3, callback);
if(retval != UA_STATUSCODE_GOOD) {
   UA_LOG_ERROR(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                 "Setting variable 3 Callback failed. StatusCode %s",
                 UA_StatusCode_name(retval));
}
return retval;
```

It follows the main server code, making use of the above definitions.

```
int main (void) {
    UA_Server *server = UA_Server_new();

    setUpEnvironment(server);

    UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return 0;
}
```

4.11 Building a Simple Client

You should already have a basic server from the previous tutorials. open62541 provides both a serverand clientside API, so creating a client is as easy as creating a server. Copy the following into a file *myClient.c*:

```
#include <open62541/client_config_default.h>
#include <open62541/client_highlevel.h>
#include <open62541/plugin/log_stdout.h>
int main(void) {
    UA_Client *client = UA_Client_new();
    UA_ClientConfig_setDefault(UA_Client_getConfig(client));
    UA_StatusCode retval = UA_Client_connect(client, "opc.tcp://localhost:4840");
    if(retval != UA_STATUSCODE_GOOD) {
        UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                    "The connection failed with status code %s",
                    UA_StatusCode_name(retval));
       UA_Client_delete(client);
        return 0;
    }
    /* Read the value attribute of the node. UA_Client_readValueAttribute is a
    * wrapper for the raw read service available as UA_Client_Service_read. */
    UA_Variant value; /* Variants can hold scalar values and arrays of any type */
    UA_Variant_init(&value);
    /* NodeId of the variable holding the current time */
    const UA_NodeId nodeId =
       UA_NODEID_NUMERIC(0, UA_NS0ID_SERVER_SERVERSTATUS_CURRENTTIME);
    retval = UA_Client_readValueAttribute(client, nodeId, &value);
    if(retval == UA_STATUSCODE_GOOD &&
       UA_Variant_hasScalarType(&value, &UA_TYPES[UA_TYPES_DATETIME])) {
       UA_DateTime raw_date = *(UA_DateTime *) value.data;
       UA_DateTimeStruct dts = UA_DateTime_toStruct(raw_date);
       UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                    "date is: %u-%u-%u %u:%u:%u.%03u",
                    dts.day, dts.month, dts.year, dts.hour,
                    dts.min, dts.sec, dts.milliSec);
    } else {
       UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_USERLAND,
                    "Reading the value failed with status code %s",
                    UA_StatusCode_name(retval));
    }
    /* Clean up */
    UA_Variant_clear(&value);
    UA_Client_delete(client); /* Disconnects the client internally */
    return 0;
}
```

Compilation is similar to the server example.

```
$ gcc -std=c99 myClient.c -lopen62541 -o myClient
```

In a MinGW environment, the Winsock library must be added.

```
$ gcc -std=c99 myClient.c -lopen62541 -lws2_32 -o myClient.exe
```

4.11.1 Further tasks

- Try to connect to some other OPC UA server by changing opc.tcp://localhost:4840 to an appropriate address (remember that the queried node is contained in any OPC UA server).
- Try to set the value of the variable node (ns=1,i="the.answer") containing an Int32 from the example server (which is built in *Building a Simple Server*) using "UA_Client_write" function. The example server needs some more modifications, i.e., changing request types. The answer can be found in examples/client.c.

4.12 Working with Publish/Subscribe

Work in progress: This Tutorial will be continuously extended during the next PubSub batches. More details about the PubSub extension and corresponding open62541 API are located here: *PubSub*.

4.12.1 Publishing Fields

The PubSub publish example demonstrates the simplest way to publish information from the information model over UDP multicast using the UADP encoding.

Connection handling

PubSubConnections can be created and deleted on runtime. More details about the system preconfiguration and connection can be found in tutorial_pubsub_connection.c.

PublishedDataSet handling

The PublishedDataSet (PDS) and PubSubConnection are the toplevel entities and can exist alone. The PDS contains the collection of the published fields. All other PubSub elements are directly or indirectly linked with the PDS or connection.

DataSetField handling

The DataSetField (DSF) is part of the PDS and describes exactly one published field.

```
static void
addDataSetField(UA_Server *server) {
    /* Add a field to the previous created PublishedDataSet */
    UA_NodeId dataSetFieldIdent;
    UA_DataSetFieldConfig dataSetFieldConfig;
    memset(&dataSetFieldConfig, 0, sizeof(UA_DataSetFieldConfig));
    dataSetFieldConfig.dataSetFieldType = UA_PUBSUB_DATASETFIELD_VARIABLE;
    dataSetFieldConfig.field.variable.fieldNameAlias = UA_STRING("Server localtime
→");
    dataSetFieldConfig.field.variable.promotedField = UA_FALSE;
    dataSetFieldConfig.field.variable.publishParameters.publishedVariable =
    UA_NODEID_NUMERIC(0, UA_NS0ID_SERVER_SERVERSTATUS_CURRENTTIME);
    dataSetFieldConfig.field.variable.publishParameters.attributeId = UA_
→ATTRIBUTEID_VALUE;
    UA_Server_addDataSetField(server, publishedDataSetIdent,
                              &dataSetFieldConfig, &dataSetFieldIdent);
```

}

WriterGroup handling

The WriterGroup (WG) is part of the connection and contains the primary configuration parameters for the message creation.

```
static void
addWriterGroup(UA_Server *server) {
    /* Now we create a new WriterGroupConfig and add the group to the existing
    * PubSubConnection. */
   UA_WriterGroupConfig writerGroupConfig;
    memset(&writerGroupConfig, 0, sizeof(UA_WriterGroupConfig));
    writerGroupConfig.name = UA_STRING("Demo WriterGroup");
    writerGroupConfig.publishingInterval = 100;
    writerGroupConfig.enabled = UA_FALSE;
    writerGroupConfig.writerGroupId = 100;
    writerGroupConfig.encodingMimeType = UA_PUBSUB_ENCODING_UADP;
    writerGroupConfig.messageSettings.encoding
                                                           = UA_EXTENSIONOBJECT_
→DECODED;
    writerGroupConfig.messageSettings.content.decoded.type = &UA_TYPES[UA_TYPES_
→UADPWRITERGROUPMESSAGEDATATYPE];
    /* The configuration flags for the messages are encapsulated inside the
     * message- and transport settings extension objects. These extension
    * objects are defined by the standard. e.g.
    * UadpWriterGroupMessageDataType */
    UA_UadpWriterGroupMessageDataType *writerGroupMessage = UA_
→UadpWriterGroupMessageDataType_new();
    /* Change message settings of writerGroup to send PublisherId,
    * WriterGroupId in GroupHeader and DataSetWriterId in PayloadHeader
    * of NetworkMessage */
    writerGroupMessage->networkMessageContentMask
                                                           = (UA_
→ UadpNetworkMessageContentMask) (UA_UADPNETWORKMESSAGECONTENTMASK_PUBLISHERID |
→ UadpNetworkMessageContentMask)UA_UADPNETWORKMESSAGECONTENTMASK_GROUPHEADER |
→UadpNetworkMessageContentMask)UA_UADPNETWORKMESSAGECONTENTMASK_WRITERGROUPID |
→ UadpNetworkMessageContentMask)UA_UADPNETWORKMESSAGECONTENTMASK_PAYLOADHEADER);
    writerGroupConfig.messageSettings.content.decoded.data = writerGroupMessage;
    UA_Server_addWriterGroup(server, connectionIdent, &writerGroupConfig, &
→writerGroupIdent);
    UA_Server_enableWriterGroup(server, writerGroupIdent);
    UA_UadpWriterGroupMessageDataType_delete(writerGroupMessage);
}
```

DataSetWriter handling

A DataSetWriter (DSW) is the glue between the WG and the PDS. The DSW is linked to exactly one PDS and contains additional information for the message generation.

That's it! You're now publishing the selected fields. Open a packet inspection tool of trust e.g. wireshark and take a look on the outgoing packages. The following graphic figures out the packages created by this tutorial.

The open62541 subscriber API will be released later. If you want to process the the datagrams, take a look on the ua_network_pubsub_networkmessage.c which already contains the decoding code for UADP messages.

It follows the main server code, making use of the above definitions.

```
addWriterGroup(server);
    addDataSetWriter(server);
    UA_StatusCode retval = UA_Server_runUntilInterrupt(server);
    UA_Server_delete(server);
    return retval == UA_STATUSCODE_GOOD ? EXIT_SUCCESS : EXIT_FAILURE;
}
static void
usage(char *progname) {
    printf("usage: %s <uri> [device]\n", progname);
}
int main(int argc, char **argv) {
    UA_String transportProfile =
        UA_STRING("http://opcfoundation.org/UA-Profile/Transport/pubsub-udp-uadp");
    UA_NetworkAddressUrlDataType networkAddressUrl =
        {UA_STRING_NULL , UA_STRING("opc.udp://224.0.0.22:4840/")};
    if (argc > 1) {
        if (strcmp(argv[1], "-h") == 0) {
            usage(argv[0]);
            return EXIT_SUCCESS;
        } else if (strncmp(argv[1], "opc.udp://", 10) == 0) {
            networkAddressUrl.url = UA_STRING(argv[1]);
        } else if (strncmp(argv[1], "opc.eth://", 10) == 0) {
            transportProfile =
                UA_STRING("http://opcfoundation.org/UA-Profile/Transport/pubsub-eth-
→uadp");
            if (argc < 3) {
                printf("Error: UADP/ETH needs an interface name\n");
                return EXIT_FAILURE;
            networkAddressUrl.url = UA_STRING(argv[1]);
        } else {
            printf("Error: unknown URI\n");
            return EXIT_FAILURE;
        }
    }
    if (argc > 2) {
        networkAddressUrl.networkInterface = UA_STRING(argv[2]);
    }
    return run(&transportProfile, &networkAddressUrl);
```

4.13 Subscribing Fields

The PubSub subscribe example demonstrates the simplest way to receive information over two transport layers such as UDP and Ethernet, that are published by tutorial_pubsub_publish example and update values in the TargetVariables of Subscriber Information Model.

```
#include <open62541/plugin/log_stdout.h>
#include <open62541/server.h>
#include <open62541/server_pubsub.h>
#include <stdio.h>
#include <stdlib.h>
UA_NodeId connectionIdentifier;
UA_NodeId readerGroupIdentifier;
UA_NodeId readerIdentifier;
UA_DataSetReaderConfig readerConfig;
static void fillTestDataSetMetaData(UA_DataSetMetaDataType *pMetaData);
/* Add new connection to the server */
static UA StatusCode
addPubSubConnection(UA_Server *server, UA_String *transportProfile,
                   UA_NetworkAddressUrlDataType *networkAddressUrl) {
    if((server == NULL) || (transportProfile == NULL) ||
        (networkAddressUrl == NULL)) {
        return UA_STATUSCODE_BADINTERNALERROR;
    }
    UA_StatusCode retval = UA_STATUSCODE_GOOD;
    /* Configuration creation for the connection */
    UA_PubSubConnectionConfig connectionConfig;
    memset (&connectionConfig, 0, sizeof(UA_PubSubConnectionConfig));
    connectionConfig.name = UA_STRING("UDPMC Connection 1");
    connectionConfig.transportProfileUri = *transportProfile;
    connectionConfig.enabled = UA_TRUE;
    UA_Variant_setScalar(&connectionConfig.address, networkAddressUrl,
                        &UA_TYPES[UA_TYPES_NETWORKADDRESSURLDATATYPE]);
    connectionConfig.publisherIdType = UA_PUBLISHERIDTYPE_UINT32;
    connectionConfig.publisherId.uint32 = UA_UInt32_random();
    retval |= UA_Server_addPubSubConnection (server, &connectionConfig, &
if (retval != UA_STATUSCODE_GOOD) {
        return retval;
    }
    return retval;
}
```

ReaderGroup

ReaderGroup is used to group a list of DataSetReaders. All ReaderGroups are created within a Pub-SubConnection and automatically deleted if the connection is removed. All network message related filters are only available in the DataSetReader.

```
/* Add ReaderGroup to the created connection */
static UA_StatusCode
addReaderGroup(UA_Server *server) {
    if(server == NULL) {
        return UA_STATUSCODE_BADINTERNALERROR;
    }
    UA_StatusCode retval = UA_STATUSCODE_GOOD;
    UA_ReaderGroupConfig readerGroupConfig;
    memset (&readerGroupConfig, 0, sizeof(UA_ReaderGroupConfig));
    readerGroupConfig.name = UA_STRING("ReaderGroup1");
    retval |= UA_Server_addReaderGroup(server, connectionIdentifier, &
→readerGroupConfig,
                                       &readerGroupIdentifier);
    UA_Server_enableReaderGroup(server, readerGroupIdentifier);
    return retval;
}
```

DataSetReader

DataSetReader can receive NetworkMessages with the DataSetMessage of interest sent by the Publisher. DataSetReader provides the configuration necessary to receive and process DataSetMessages on the Subscriber side. DataSetReader must be linked with a SubscribedDataSet and be contained within a ReaderGroup.

```
/* Add DataSetReader to the ReaderGroup */
static UA_StatusCode
addDataSetReader(UA_Server *server) {
    if(server == NULL) {
        return UA_STATUSCODE_BADINTERNALERROR;
    }
    UA_StatusCode retval = UA_STATUSCODE_GOOD;
    memset (&readerConfig, 0, sizeof(UA_DataSetReaderConfig));
    readerConfig.name = UA_STRING("DataSet Reader 1");
    /* Parameters to filter which DataSetMessage has to be processed
    * by the DataSetReader */
    /* The following parameters are used to show that the data published by
    * tutorial_pubsub_publish.c is being subscribed and is being updated in
    * the information model */
    UA_UInt16 publisherIdentifier = 2234;
    readerConfig.publisherId.type = &UA_TYPES_UINT16];
    readerConfig.publisherId.data = &publisherIdentifier;
    readerConfig.writerGroupId
    readerConfig.dataSetWriterId = 62541;
```

SubscribedDataSet

Set SubscribedDataSet type to TargetVariables data type. Add subscribedvariables to the DataSetReader

```
static UA_StatusCode
addSubscribedVariables (UA_Server *server, UA_NodeId dataSetReaderId) {
   if(server == NULL)
        return UA_STATUSCODE_BADINTERNALERROR;
   UA_StatusCode retval = UA_STATUSCODE_GOOD;
   UA_NodeId folderId;
   UA_String folderName = readerConfig.dataSetMetaData.name;
   UA_ObjectAttributes oAttr = UA_ObjectAttributes_default;
   UA_QualifiedName folderBrowseName;
   if(folderName.length > 0) {
       oAttr.displayName.locale = UA_STRING ("en-US");
        oAttr.displayName.text = folderName;
        folderBrowseName.namespaceIndex = 1;
        folderBrowseName.name = folderName;
   }
   else {
       oAttr.displayName = UA_LOCALIZEDTEXT ("en-US", "Subscribed Variables");
        folderBrowseName = UA_QUALIFIEDNAME (1, "Subscribed Variables");
   }
   UA_Server_addObjectNode (server, UA_NODEID_NULL,
                             UA_NODEID_NUMERIC (0, UA_NS0ID_OBJECTSFOLDER),
                             UA_NODEID_NUMERIC (0, UA_NS0ID_ORGANIZES),
                             folderBrowseName, UA_NODEID_NUMERIC (0,
                             UA_NS0ID_BASEOBJECTTYPE), oAttr, NULL, &folderId);
```

TargetVariables

The SubscribedDataSet option TargetVariables defines a list of Variable mappings between received DataSet fields and target Variables in the Subscriber AddressSpace. The values subscribed from the Publisher are updated in the value field of these variables

```
/* Create the TargetVariables with respect to DataSetMetaData fields */
UA_FieldTargetVariable *targetVars = (UA_FieldTargetVariable *)

UA_calloc(readerConfig.dataSetMetaData.fieldsSize, sizeof(UA_
→FieldTargetVariable));
```

```
for(size_t i = 0; i < readerConfig.dataSetMetaData.fieldsSize; i++) {</pre>
        /* Variable to subscribe data */
        UA_VariableAttributes vAttr = UA_VariableAttributes_default;
        UA_LocalizedText_copy(&readerConfig.dataSetMetaData.fields[i].description,
                              &vAttr.description);
        vAttr.displayName.locale = UA_STRING("en-US");
        vAttr.displayName.text = readerConfig.dataSetMetaData.fields[i].name;
        vAttr.dataType = readerConfig.dataSetMetaData.fields[i].dataType;
        UA_NodeId newNode;
        retval |= UA_Server_addVariableNode(server, UA_NODEID_NUMERIC(1, (UA_
\rightarrowUInt32)i + 50000),
                                            folderId,
                                            UA_NODEID_NUMERIC(0, UA_NS0ID_
→ HASCOMPONENT),
                                            UA_QUALIFIEDNAME(1, (char *)readerConfig.
→dataSetMetaData.fields[i].name.data),
                                            UA_NODEID_NUMERIC(0, UA_NS0ID_
→BASEDATAVARIABLETYPE),
                                            vAttr, NULL, &newNode);
        /* For creating Targetvariables */
        UA_FieldTargetDataType_init(&targetVars[i].targetVariable);
        targetVars[i].targetVariable.attributeId = UA_ATTRIBUTEID_VALUE;
        targetVars[i].targetVariable.targetNodeId = newNode;
    }
    retval = UA_Server_DataSetReader_createTargetVariables(server, dataSetReaderId,
                                                            readerConfig.
→dataSetMetaData.fieldsSize, targetVars);
    for(size_t i = 0; i < readerConfig.dataSetMetaData.fieldsSize; i++)</pre>
        UA_FieldTargetDataType_clear(&targetVars[i].targetVariable);
    UA_free(targetVars);
    UA_free(readerConfig.dataSetMetaData.fields);
    return retval;
}
```

DataSetMetaData

The DataSetMetaData describes the content of a DataSet. It provides the information necessary to decode DataSetMessages on the Subscriber side. DataSetMessages received from the Publisher are decoded into DataSet and each field is updated in the Subscriber based on datatype match of Target-Variable fields of Subscriber and PublishedDataSetFields of Publisher

```
/* Define MetaData for TargetVariables */
static void fillTestDataSetMetaData(UA_DataSetMetaDataType *pMetaData) {
   if(pMetaData == NULL) {
      return;
   }
   (continues on next page)
```

```
UA_DataSetMetaDataType_init (pMetaData);
    pMetaData->name = UA_STRING ("DataSet 1");
    /* Static definition of number of fields size to 4 to create four different
    * targetVariables of distinct datatype
    * Currently the publisher sends only DateTime data type */
    pMetaData->fieldsSize = 4;
    pMetaData->fields = (UA_FieldMetaData*)UA_Array_new (pMetaData->fieldsSize,
                         &UA_TYPES[UA_TYPES_FIELDMETADATA]);
    /* DateTime DataType */
    UA_FieldMetaData_init (&pMetaData->fields[0]);
    UA_NodeId_copy (&UA_TYPES[UA_TYPES_DATETIME].typeId,
                    &pMetaData->fields[0].dataType);
    pMetaData->fields[0].builtInType = UA_NS0ID_DATETIME;
    pMetaData->fields[0].name = UA_STRING ("DateTime");
    pMetaData->fields[0].valueRank = -1; /* scalar */

```

CHAPTER

FIVE

DATA TYPES

The OPC UA protocol defines 25 builtin data types and three ways of combining them into higher-order types: arrays, structures and unions. In open62541, only the builtin data types are defined manually. All other data types are generated from standard XML definitions. Their exact definitions can be looked up at https://opcfoundation.org/UA/schemas/Opc.Ua.Types.bsd.

For users that are new to open62541, take a look at the *tutorial for working with data types* before diving into the implementation details.

5.1 Builtin Types

5.1.1 Boolean

A two-state logical value (true or false).

```
typedef bool UA_Boolean;
#define UA_TRUE true UA_INTERNAL_DEPRECATED
#define UA_FALSE false UA_INTERNAL_DEPRECATED
```

5.1.2 SByte

An integer value between -128 and 127.

```
typedef int8_t UA_SByte;
#define UA_SBYTE_MIN (-128)
#define UA_SBYTE_MAX 127
```

5.1.3 Byte

An integer value between 0 and 255.

```
typedef uint8_t UA_Byte;
#define UA_BYTE_MIN 0
#define UA_BYTE_MAX 255
```

5.1.4 Int16

An integer value between -32 768 and 32 767.

```
typedef int16_t UA_Int16;
#define UA_INT16_MIN (-32768)
#define UA_INT16_MAX 32767
```

5.1.5 UInt16

An integer value between 0 and 65 535.

```
typedef uint16_t UA_UInt16;
#define UA_UINT16_MIN 0
#define UA_UINT16_MAX 65535
```

5.1.6 Int32

An integer value between -2 147 483 648 and 2 147 483 647.

```
typedef int32_t UA_Int32;
#define UA_INT32_MIN ((int32_t)-2147483648LL)
#define UA_INT32_MAX 2147483647L
```

5.1.7 UInt32

An integer value between 0 and 4 294 967 295.

```
typedef uint32_t UA_UInt32;
#define UA_UINT32_MIN 0
#define UA_UINT32_MAX 4294967295UL
```

5.1.8 Int64

An integer value between -9 223 372 036 854 775 808 and 9 223 372 036 854 775 807.

```
typedef int64_t UA_Int64;
#define UA_INT64_MAX (int64_t)9223372036854775807LL
#define UA_INT64_MIN ((int64_t)-UA_INT64_MAX-1LL)
```

5.1.9 UInt64

An integer value between 0 and 18 446 744 073 709 551 615.

```
typedef uint64_t UA_UInt64;
#define UA_UINT64_MIN 0
#define UA_UINT64_MAX (uint64_t)18446744073709551615ULL
```

5.1.10 Float

An IEEE single precision (32 bit) floating point value.

```
typedef float UA_Float;
#define UA_FLOAT_MIN FLT_MIN;
#define UA_FLOAT_MAX FLT_MAX;
```

5.1.11 Double

An IEEE double precision (64 bit) floating point value.

```
typedef double UA_Double;
#define UA_DOUBLE_MIN DBL_MIN;
#define UA_DOUBLE_MAX DBL_MAX;
```

5.1.12 StatusCode

A numeric identifier for an error or condition that is associated with a value or an operation. See the section statuscodes for the meaning of a specific code.

Each StatusCode has one of three "severity" bit-flags: Good, Uncertain, Bad. An additional reason is indicated by the SubCode bitfield.

- A StatusCode with severity Good means that the value is of good quality.
- A StatusCode with severity Uncertain means that the quality of the value is uncertain for reasons indicated by the SubCode.
- A StatusCode with severity Bad means that the value is not usable for reasons indicated by the SubCode.

```
typedef uint32_t UA_StatusCode;

/* Returns the human-readable name of the StatusCode. If no matching StatusCode
  * is found, a default string for "Unknown" is returned. This feature might be
  * disabled to create a smaller binary with the
  * UA_ENABLE_STATUSCODE_DESCRIPTIONS build-flag. Then the function returns an
  * empty string for every StatusCode. */
const char *
UA_StatusCode_name(UA_StatusCode code);
```

```
/* Extracts the severity from a StatusCode. See Part 4, Section 7.34 for
* details. */
UA_INLINABLE(UA_Boolean
             UA_StatusCode_isBad(UA_StatusCode code), {
    return ((code >> 30) >= 0x02);
})
UA_INLINABLE(UA_Boolean
             UA_StatusCode_isUncertain(UA_StatusCode code), {
    return ((code \gg 30) == 0x01);
})
UA_INLINABLE(UA_Boolean
             UA_StatusCode_isGood(UA_StatusCode code), {
    return ((code \gg 30) == 0x00);
})
/* Compares the top 16 bits of two StatusCodes for equality. This should only
* be used when processing user-defined StatusCodes e.g when processing a_
→ReadResponse.
* As a convention, the lower bits of StatusCodes should not be used internally,
→meaning
* can compare them without the use of this function. */
UA_INLINABLE(UA_Boolean
             UA_StatusCode_isEqualTop(UA_StatusCode s1, UA_StatusCode s2), {
    return ((s1 & 0xFFFF0000) == (s2 & 0xFFFF0000));
})
```

5.1.13 String

A sequence of Unicode characters. Strings are just an array of UA_Byte.

```
typedef struct {
    size_t length; /* The length of the string */
    UA_Byte *data; /* The content (not null-terminated) */
} UA_String;

/* Copies the content on the heap. Returns a null-string when alloc fails */
UA_String
UA_String_fromChars(const char *src);

UA_Boolean
UA_String_isEmpty(const UA_String *s);

extern const UA_String UA_STRING_NULL;
```

UA_STRING returns a string pointing to the original char-array. UA_STRING_ALLOC is shorthand for UA_String_fromChars and makes a copy of the char-array.

5.1.14 DateTime

An instance in time. A DateTime value is encoded as a 64-bit signed integer which represents the number of 100 nanosecond intervals since January 1, 1601 (UTC).

The methods providing an interface to the system clock are architecture- specific. Usually, they provide a UTC clock that includes leap seconds. The OPC UA standard allows the use of International Atomic Time (TAI) for the DateTime instead. But this is still unusual and not implemented for most SDKs. Currently (2019), UTC and TAI are 37 seconds apart due to leap seconds.

```
typedef int64_t UA_DateTime;
/* Multiples to convert durations to DateTime */
#define UA_DATETIME_USEC 10LL
#define UA_DATETIME_MSEC (UA_DATETIME_USEC * 1000LL)
#define UA_DATETIME_SEC (UA_DATETIME_MSEC * 1000LL)
/* The current time in UTC time */
UA_DateTime UA_DateTime_now(void);
/* Offset between local time and UTC time */
UA_Int64 UA_DateTime_localTimeUtcOffset(void);
/* CPU clock invariant to system time changes. Use only to measure durations,
* not absolute time. */
UA_DateTime UA_DateTime_nowMonotonic(void);
/* Represents a Datetime as a structure */
typedef struct UA_DateTimeStruct {
    UA_UInt16 nanoSec;
    UA_UInt16 microSec;
    UA_UInt16 milliSec;
    UA_UInt16 sec:
    UA_UInt16 min;
```

```
UA_UInt16 hour;
    UA_UInt16 day; /* From 1 to 31 */
    UA_UInt16 month; /* From 1 to 12 */
    UA_Int16 year; /* Can be negative (BC) */
} UA_DateTimeStruct;
UA_DateTimeStruct UA_DateTime_toStruct(UA_DateTime t);
UA_DateTime UA_DateTime_fromStruct(UA_DateTimeStruct ts);
/* The C99 standard (7.23.1) says: "The range and precision of times
* representable in clock_t and time_t are implementation-defined." On most
* systems, time_t is a 4 or 8 byte integer counting seconds since the UTC Unix
* epoch. The following methods are used for conversion. */
/* Datetime of 1 Jan 1970 00:00 */
#define UA_DATETIME_UNIX_EPOCH (11644473600LL * UA_DATETIME_SEC)
UA_INLINABLE(UA_Int64
             UA_DateTime_toUnixTime(UA_DateTime date), {
    return (date - UA_DATETIME_UNIX_EPOCH) / UA_DATETIME_SEC;
})
UA_INLINABLE(UA_DateTime
             UA_DateTime_fromUnixTime(UA_Int64 unixDate), {
    return (unixDate * UA_DATETIME_SEC) + UA_DATETIME_UNIX_EPOCH;
})
```

5.1.15 Guid

A 16 byte value that can be used as a globally unique identifier.

5.1.16 ByteString

A sequence of octets.

```
typedef UA_String UA_ByteString;
extern const UA_ByteString UA_BYTESTRING_NULL;
/* Allocates memory of size length for the bytestring.
* The content is not set to zero. */
UA_StatusCode
UA_ByteString_allocBuffer(UA_ByteString *bs, size_t length);
/* Converts a ByteString to the corresponding
* base64 representation */
UA_StatusCode
UA_ByteString_toBase64(const UA_ByteString *bs, UA_String *output);
/* Parse a ByteString from a base64 representation */
UA_StatusCode
UA_ByteString_fromBase64(UA_ByteString *bs,
                         const UA_String *input);
#define UA_BYTESTRING(chars) UA_STRING(chars)
#define UA_BYTESTRING_ALLOC(chars) UA_STRING_ALLOC(chars)
/* Returns a non-cryptographic hash of a bytestring */
UA_UInt32
UA_ByteString_hash(UA_UInt32 initialHashValue,
                   const UA_Byte *data, size_t size);
```

5.1.17 XmlElement

An XML element.

```
typedef UA_String UA_XmlElement;
```

5.1.18 Nodeld

An identifier for a node in the address space of an OPC UA Server.

```
enum UA_NodeIdType {
    UA_NODEIDTYPE_NUMERIC
                             = 0, /* In the binary encoding, this can also
                                   * become 1 or 2 (two-byte and four-byte
                                   * encoding of small numeric nodeids) */
    UA_NODEIDTYPE_STRING
                             = 3,
    UA_NODEIDTYPE_GUID
                             = 4,
    UA_NODEIDTYPE_BYTESTRING = 5
};
typedef struct {
    UA_UInt16 namespaceIndex;
    enum UA_NodeIdType identifierType;
    union {
       UA_UInt32
                     numeric;
       UA_String
                     string;
       UA_Guid
                     guid;
       UA_ByteString byteString;
    } identifier;
} UA_NodeId;
extern const UA_NodeId UA_NODEID_NULL;
UA_Boolean UA_NodeId_isNull(const UA_NodeId *p);
/* Print the NodeId in the human-readable format defined in Part 6,
* 5.3.1.10.
* Examples:
* UA_NODEID("i=13")
* UA_NODEID("ns=10;i=1")
* UA_NODEID("ns=10;s=Hello:World")
* UA_NODEID("g=09087e75-8e5e-499b-954f-f2a9603db28a")
   UA_NODEID("ns=1;b=b3BlbjYyNTQxIQ==") // base64
* The method can either use a pre-allocated string buffer or allocates memory
* internally if called with an empty output string. */
UA StatusCode
UA_NodeId_print(const UA_NodeId *id, UA_String *output);
/* Parse the human-readable NodeId format. Attention! String and
```

The following methods are a shorthand for creating Nodelds.

```
UA_INLINABLE(UA_NodeId
             UA_NODEID_NUMERIC(UA_UInt16 nsIndex,
                               UA_UInt32 identifier), {
    UA_NodeId id;
    memset(&id, 0, sizeof(UA_NodeId));
    id.namespaceIndex = nsIndex;

UA_Order
UA_ExpandedNodeId_order(const UA_ExpandedNodeId *n1,
                        const UA_ExpandedNodeId *n2);
/* Returns a non-cryptographic hash for ExpandedNodeId. The hash of an
* ExpandedNodeId is identical to the hash of the embedded (simple) NodeId if
* the ServerIndex is zero and no NamespaceUri is set. */
UA_UInt32
UA_ExpandedNodeId_hash(const UA_ExpandedNodeId *n);
```

5.1.20 QualifiedName

A name qualified by a namespace.

```
typedef struct {
    UA_UInt16 namespaceIndex;
    UA_String name;
} UA_QualifiedName;
UA_INLINABLE(UA_Boolean
             UA_QualifiedName_isNull(const UA_QualifiedName *q), {
    return (q->namespaceIndex == 0 && q->name.length == 0);
})
/* Returns a non-cryptographic hash for QualifiedName */
UA_UInt32
UA_QualifiedName_hash(const UA_QualifiedName *q);
UA_INLINABLE(UA_QualifiedName
             UA_QUALIFIEDNAME(UA_UInt16 nsIndex, char *chars), {
    UA_QualifiedName qn;
    qn.namespaceIndex = nsIndex;
    qn.name = UA_STRING(chars);
    return qn;
})
UA_INLINABLE(UA_QualifiedName
             UA_QUALIFIEDNAME_ALLOC(UA_UInt16 nsIndex, const char *chars), {
    UA_QualifiedName qn;
    qn.namespaceIndex = nsIndex;
    qn.name = UA_STRING_ALLOC(chars);
    return qn;
})
```

5.1.21 LocalizedText

Human readable text with an optional locale identifier.

5.1.22 NumericRange

NumericRanges are used to indicate subsets of a (multidimensional) array. They no official data type in the OPC UA standard and are transmitted only with a string encoding, such as "1:2,0:3,5". The colon separates min/max index and the comma separates dimensions. A single value indicates a range with a single element (min==max).

```
typedef struct {
    UA_UInt32 min;
    UA_UInt32 max;
} UA_NumericRangeDimension;
typedef struct {
    size_t dimensionsSize;
    UA_NumericRangeDimension *dimensions;
} UA_NumericRange;
UA_StatusCode
UA_NumericRange_parse(UA_NumericRange *range, const UA_String str);
UA_INLINABLE(UA_NumericRange
             UA_NUMERICRANGE(const char *s), {
    UA_NumericRange nr;
    memset(&nr, 0, sizeof(nr));
    UA_NumericRange_parse(&nr, UA_STRING((char*)(uintptr_t)s));
    return nr;
})
```

5.1.23 Variant

Variants may contain values of any type together with a description of the content. See the section on *Generic Type Handling* on how types are described. The standard mandates that variants contain built-in data types only. If the value is not of a builtin type, it is wrapped into an *ExtensionObject*. open62541 hides this wrapping transparently in the encoding layer. If the data type is unknown to the receiver, the variant contains the original ExtensionObject in binary or XML encoding.

Variants may contain a scalar value or an array. For details on the handling of arrays, see the section on *Array handling*. Array variants can have an additional dimensionality (matrix, 3-tensor, ...) defined in an array of dimension lengths. The actual values are kept in an array of dimensions one. For

users who work with higher-dimensions arrays directly, keep in mind that dimensions of higher rank are serialized first (the highest rank dimension has stride 1 and elements follow each other directly). Usually it is simplest to interact with higher-dimensional arrays via UA_NumericRange descriptions (see *Array handling*).

To differentiate between scalar / array variants, the following definition is used. UA_Variant_isScalar provides simplified access to these checks.

```
    arrayLength == 0 && data == NULL: undefined array of length -1
    arrayLength == 0 && data == UA_EMPTY_ARRAY_SENTINEL: array of length 0
    arrayLength == 0 && data > UA_EMPTY_ARRAY_SENTINEL: scalar value
```

Variants can also be *empty*. Then, the pointer to the type description is NULL.

• arrayLength > 0: array of the given length

```
/* Forward declaration. See the section on Generic Type Handling */
struct UA DataType:
typedef struct UA_DataType UA_DataType;
#define UA_EMPTY_ARRAY_SENTINEL ((void*)0x01)
typedef enum {
    UA_VARIANT_DATA,
                      /* The data has the same lifecycle as the variant */
    UA_VARIANT_DATA_NODELETE /* The data is "borrowed" by the variant and is
                             * not deleted when the variant is cleared up.
                             * The array dimensions also borrowed. */
} UA_VariantStorageType;
typedef struct {
    const UA_DataType *type;
                               /* The data type description */
   UA_VariantStorageType storageType;
                           /* The number of elements in the data array */
   size_t arrayLength;
   void *data;
                                /* Points to the scalar or array data */

* @param v The variant
```

5.1.24 ExtensionObject

ExtensionObjects may contain scalars of any data type. Even those that are unknown to the receiver. See the section on *Generic Type Handling* on how types are described. If the received data type is unknown, the encoded string and target Nodeld is stored instead of the decoded value.

```
typedef enum {
    UA_EXTENSIONOBJECT_ENCODED_NOBODY
    UA_EXTENSIONOBJECT_ENCODED_BYTESTRING = 1,
    UA_EXTENSIONOBJECT_ENCODED_XML
                                         = 2,
   UA_EXTENSIONOBJECT_DECODED
                                         = 3,
    UA_EXTENSIONOBJECT_DECODED_NODELETE = 4 /* Don't delete the content
                                                 together with the
                                                 ExtensionObject */
} UA_ExtensionObjectEncoding;
typedef struct {
    UA_ExtensionObjectEncoding encoding;
    union {
        struct {
            UA_NodeId typeId; /* The nodeid of the datatype */
            UA_ByteString body; /* The bytestring of the encoded data */
        } encoded;
        struct {
            const UA_DataType *type;
            void *data;
        } decoded;
    } content;
} UA_ExtensionObject;
/* Initialize the ExtensionObject and set the "decoded" value to the given
* pointer. The value will be deleted when the ExtensionObject is cleared. */
UA_ExtensionObject_setValue(UA_ExtensionObject *eo,
                            void *p,
                            const UA_DataType *type);
/* Initialize the ExtensionObject and set the "decoded" value to the given
* pointer. The value will *not* be deleted when the ExtensionObject is
```

5.1.25 DataValue

A data value with an associated status code and timestamps.

```
typedef struct {
   UA_Variant
               value;
   UA_DateTime sourceTimestamp;
   UA_DateTime serverTimestamp;
   UA_UInt16
               sourcePicoseconds;
   UA_UInt16
                 serverPicoseconds;
   UA_StatusCode status;
   UA Boolean hasValue
                                      : 1;
   UA_Boolean hasStatus
                                      : 1;
   UA_Boolean hasSourceTimestamp
                                    : 1;
   UA_Boolean
                 hasServerTimestamp
   UA_Boolean hasSourcePicoseconds : 1;
   UA_Boolean hasServerPicoseconds : 1;
} UA_DataValue;
/* Copy the DataValue, but use only a subset of the (multidimensional) array of
* of the variant of the source DataValue. Returns an error code if the variant
* of the DataValue is not an array or if the indicated range does not fit.
* @param src The source DataValue
* @param dst The target DataValue
* @param range The range of the variant of the DataValue to copy
* @return Returns UA_STATUSCODE_GOOD or an error code */
UA_StatusCode
UA_DataValue_copyVariantRange(const UA_DataValue *src, UA_DataValue *dst,
                             const UA_NumericRange range);
```

5.1.26 DiagnosticInfo

A structure that contains detailed error and diagnostic information associated with a StatusCode.

```
typedef struct UA_DiagnosticInfo {
    UA_Boolean
                 hasSymbolicId
                                        : 1;
    UA_Boolean
                 hasNamespaceUri
                                        : 1;
    UA_Boolean
                 hasLocalizedText
                                        : 1;
    UA_Boolean
                 hasLocale
                                        : 1;
    UA_Boolean
                 hasAdditionalInfo
                                        : 1;
    UA Boolean
                 hasInnerStatusCode
                                        : 1;
    UA_Boolean
                 hasInnerDiagnosticInfo : 1;
                 symbolicId;
    UA_Int32
   UA_Int32
                 namespaceUri;
                 localizedText;
   UA_Int32
   UA_Int32
                 locale;
    UA_String
                 additionalInfo;
    UA_StatusCode innerStatusCode;
    struct UA_DiagnosticInfo *innerDiagnosticInfo;
} UA_DiagnosticInfo;
```

5.2 Generic Type Handling

All information about a (builtin/structured) data type is stored in a UA_DataType. The array UA_TYPES contains the description of all standard-defined types. This type description is used for the following generic operations that work on all types:

- void T_init(T *ptr): Initialize the data type. This is synonymous with zeroing out the memory, i.e. memset(ptr, 0, sizeof(T)).
- T* T_new(): Allocate and return the memory for the data type. The value is already initialized.
- UA_StatusCode T_copy(const T *src, T *dst): Copy the content of the data type. Returns UA_STATUSCODE_GOOD or UA_STATUSCODE_BADOUTOFMEMORY.
- void T_clear(T *ptr): Delete the dynamically allocated content of the data type and perform a T_init to reset the type.
- void T_delete(T *ptr): Delete the content of the data type and the memory for the data type itself
- void T_equal(T *p1, T *p2): Compare whether p1 and p2 have identical content. You can use UA_order if an absolute ordering is required.

Specializations, such as UA_Int32_new() are derived from the generic type operations as static inline functions.

```
member element? For arrays this is the
                                     padding before the size_t length member.
                                     (No padding between size_t and the
                                     following ptr.) For unions, the padding
                                     includes the size of the switchfield (the
                                     offset from the start of the union
                                     type). */
    UA_Byte isArray : 1;
                                  /* The member is an array */
    UA_Byte isOptional : 1;
                                /* The member is an optional field */
} UA_DataTypeMember;

Builtin data types can be accessed as UA_TYPES[UA_TYPES_XXX], where XXX is the name of the data type. If only the NodeId of a type is known, use the following method to retrieve the data type description.

The following functions are used for generic handling of data types.

```
/* Allocates and initializes a variable of type dataType
* @param type The datatype description
* @return Returns the memory location of the variable or NULL if no
         memory could be allocated */
void * UA_new(const UA_DataType *type);
/* Initializes a variable to default values
* @param p The memory location of the variable
* @param type The datatype description */
UA_INLINABLE(void
             UA_init(void *p, const UA_DataType *type), {
   memset(p, 0, type->memSize);
})
/* Copies the content of two variables. If copying fails (e.g. because no memory
* was available for an array), then dst is emptied and initialized to prevent
* memory leaks.
* @param src The memory location of the source variable
* @param dst The memory location of the destination variable
* @param type The datatype description
\star @return Indicates whether the operation succeeded or returns an error code \star/
UA_copy(const void *src, void *dst, const UA_DataType *type);
/* Deletes the dynamically allocated content of a variable (e.g. resets all
* arrays to undefined arrays). Afterwards, the variable can be safely deleted
* without causing memory leaks. But the variable is not initialized and may
* contain old data that is not memory-relevant.
* @param p The memory location of the variable
* @param type The datatype description of the variable */
void UA_clear(void *p, const UA_DataType *type);
```

```
#define UA_deleteMembers(p, type) UA_clear(p, type)
/* Frees a variable and all of its content.
* @param p The memory location of the variable
* @param type The datatype description of the variable */
void UA_delete(void *p, const UA_DataType *type);
/* Pretty-print the value from the datatype. The output is pretty-printed JSON5.
* Note that this format is non-standard and should not be sent over the
* network. It can however be read by our own JSON decoding.
* @param p The memory location of the variable
* @param type The datatype description of the variable
* @param output A string that is used for the pretty-printed output. If the
          memory for string is already allocated, we try to use the existing
          string (the length is adjusted). If the string is empty, memory
          is allocated for it.
* @return Indicates whether the operation succeeded */
#ifdef UA_ENABLE_JSON_ENCODING

#endif
/* Compare two values and return their order.
* For numerical types (including StatusCodes and Enums), their natural order is
* used. NaN is the "smallest" value for floating point values. Different bit
* representations of NaN are considered identical.
* All other types have *some* absolute ordering so that a < b, b < c -> a < c.
* The ordering of arrays (also strings) is in "shortlex": A shorter array is
* always smaller than a longer array. Otherwise the first different element
* defines the order.
* When members of different types are permitted (in Variants and
* ExtensionObjects), the memory address in the "UA_DataType*" pointer
* determines which variable is smaller.
* @param p1 The memory location of the first value
* @param p2 The memory location of the first value
* @param type The datatype description of both values */
UA_Order
UA_order(const void *p1, const void *p2, const UA_DataType *type);
/* Compare if two values have identical content. */
UA_INLINABLE(UA_Boolean
             UA_equal(const void *p1, const void *p2, const UA_DataType *type), {
```

```
return (UA_order(p1, p2, type) == UA_ORDER_EQ);
})
```

5.3 Binary Encoding/Decoding

Encoding and decoding routines for the binary format. For the binary decoding additional data types can be forwarded.

```
/* Returns the number of bytes the value p takes in binary encoding. Returns
* zero if an error occurs. */
size t
UA_calcSizeBinary(const void *p, const UA_DataType *type);
/* Encodes a data-structure in the binary format. If outBuf has a length of
* zero, a buffer of the required size is allocated. Otherwise, encoding into
* the existing outBuf is attempted (and may fail if the buffer is too
* small). */
UA_StatusCode
UA_encodeBinary(const void *p, const UA_DataType *type,
                UA_ByteString *outBuf);
/* The structure with the decoding options may be extended in the future.
* Zero-out the entire structure initially to ensure code-compatibility when
* more fields are added in a later release. */
typedef struct {
    const UA_DataTypeArray *customTypes; /* Begin of a linked list with custom
                                          * datatype definitions */
} UA_DecodeBinaryOptions;
/* Decodes a data structure from the input buffer in the binary format. It is
* assumed that `p` points to valid memory (not necessarily zeroed out). The
* options can be NULL and will be disregarded in that case. */
UA_StatusCode
UA_decodeBinary(const UA_ByteString *inBuf,
                void *p, const UA_DataType *type,
                const UA_DecodeBinaryOptions *options);
```

5.4 JSON En/Decoding

The JSON decoding can parse the official encoding from the OPC UA specification. It further allows the following extensions:

- The strict JSON format is relaxed to also allow the JSON5 extensions (https://json5.org/). This allows for more human-readable encoding and adds convenience features such as trailing commas in arrays and comments within JSON documents.
- Int64/UInt64 don't necessarily have to be wrapped into a string.

• If *UA_ENABLE_PARSING* is set, Nodelds and ExpandedNodelds can be given in the string encoding (e.g. "ns=1;i=42", see *UA_Nodeld_parse*). The standard encoding is to express Nodelds as JSON objects.

These extensions are not intended to be used for the OPC UA protocol on the network. They were rather added to allow more convenient configuration file formats that also include data in the OPC UA type system.

```
#ifdef UA_ENABLE_JSON_ENCODING
typedef struct {
    const UA_String *namespaces;
    size_t namespacesSize;
    const UA_String *serverUris;
    size_t serverUrisSize;
   UA_Boolean useReversible;
   UA_Boolean prettyPrint; /* Add newlines and spaces for legibility */
    /* Enabling the following options leads to non-standard compatible JSON5
    * encoding! Use it for pretty-printing, but not for sending messages over
    * the network. (Our own decoding can still parse it.) */
    UA_Boolean unquotedKeys; /* Don't print quotes around object element keys */
    UA_Boolean stringNodeIds; /* String encoding for NodeIds, like "ns=1;i=42" */
} UA_EncodeJsonOptions;
/* Returns the number of bytes the value src takes in json encoding. Returns
* zero if an error occurs. */
size_t
UA_calcSizeJson(const void *src, const UA_DataType *type,
                const UA_EncodeJsonOptions *options);
/* Encodes the scalar value described by type to json encoding.
* @param src The value. Must not be NULL.
* @param type The value type. Must not be NULL.
* @param outBuf Pointer to ByteString containing the result if the encoding
          was successful
* @return Returns a statuscode whether encoding succeeded. */
UA_StatusCode
UA_encodeJson(const void *src, const UA_DataType *type, UA_ByteString *outBuf,
              const UA_EncodeJsonOptions *options);
/* The structure with the decoding options may be extended in the future.
* Zero-out the entire structure initially to ensure code-compatibility when
* more fields are added in a later release. */
typedef struct {
    const UA_String *namespaces;
    size_t namespacesSize;
    const UA_String *serverUris;
```

```
size t serverUrisSize:
    const UA_DataTypeArray *customTypes; /* Begin of a linked list with custom
                                          * datatype definitions */
} UA_DecodeJsonOptions;
/* Decodes a scalar value described by type from json encoding.
* @param src The buffer with the json encoded value. Must not be NULL.
* @param dst The target value. Must not be NULL. The target is assumed to have
          size type->memSize. The value is reset to zero before decoding. If
          decoding fails, members are deleted and the value is reset (zeroed)
          again.
* @param type The value type. Must not be NULL.
* @param options The options struct for decoding, currently unused
* @return Returns a statuscode whether decoding succeeded. */
UA_StatusCode
UA_decodeJson(const UA_ByteString *src, void *dst, const UA_DataType *type,
              const UA_DecodeJsonOptions *options);
#endif /* UA_ENABLE_JSON_ENCODING */
```

5.5 XML En/Decoding

The XML decoding can parse the official encoding from the OPC UA specification.

These extensions are not intended to be used for the OPC UA protocol on the network. They were rather added to allow more convenient configuration file formats that also include data in the OPC UA type system.

```
UA StatusCode
UA_encodeXml(const void *src, const UA_DataType *type, UA_ByteString *outBuf,
             const UA_EncodeXmlOptions *options);
/* The structure with the decoding options may be extended in the future.
* Zero-out the entire structure initially to ensure code-compatibility when
* more fields are added in a later release. */
typedef struct {
    const UA_DataTypeArray *customTypes; /* Begin of a linked list with custom
                                         * datatype definitions */
} UA_DecodeXmlOptions;
/* Decodes a scalar value described by type from xml encoding.
* @param src The buffer with the xml encoded value. Must not be NULL.
* @param dst The target value. Must not be NULL. The target is assumed to have
          size type->memSize. The value is reset to zero before decoding. If
          decoding fails, members are deleted and the value is reset (zeroed)
          again.
* @param type The value type. Must not be NULL.
* @param options The options struct for decoding, currently unused
* @return Returns a statuscode whether decoding succeeded. */
UA StatusCode
UA_decodeXml(const UA_ByteString *src, void *dst, const UA_DataType *type,
             const UA_DecodeXmlOptions *options);
#endif /* UA_ENABLE_XML_ENCODING */
```

5.6 Array handling

In OPC UA, arrays can have a length of zero or more with the usual meaning. In addition, arrays can be undefined. Then, they don't even have a length. In the binary encoding, this is indicated by an array of length -1.

In open62541 however, we use size_t for array lengths. An undefined array has length 0 and the data pointer is NULL. An array of length 0 also has length 0 but a data pointer UA_EMPTY_ARRAY_SENTINEL.

```
/* Allocates and initializes an array of variables of a specific type
    *
    * @param size The requested array length
    * @param type The datatype description
    * @return Returns the memory location of the variable or NULL if no memory
    * could be allocated */
    void *
UA_Array_new(size_t size, const UA_DataType *type);

/* Allocates and copies an array
    *
```

```
* @param src The memory location of the source array
* @param size The size of the array
* @param dst The location of the pointer to the new array
* @param type The datatype of the array members
* @return Returns UA_STATUSCODE_GOOD or UA_STATUSCODE_BADOUTOFMEMORY */
UA StatusCode
UA_Array_copy(const void *src, size_t size, void **dst,
             const UA_DataType *type);
/* Resizes (and reallocates) an array. The last entries are initialized to zero
* if the array length is increased. If the array length is decreased, the last
* entries are removed if the size is decreased.
* @param p Double pointer to the array memory. Can be overwritten by the result
           of a realloc.
* @param size The current size of the array. Overwritten in case of success.
* @param newSize The new size of the array
* @param type The datatype of the array members
* @return Returns UA_STATUSCODE_GOOD or UA_STATUSCODE_BADOUTOFMEMORY. The
           original array is left untouched in the failure case. */
UA_StatusCode
UA_Array_resize(void **p, size_t *size, size_t newSize,
               const UA_DataType *type);
/* Append the given element at the end of the array. The content is moved
* (shallow copy) and the original memory is _init'ed if appending is
* successful.
* @param p Double pointer to the array memory. Can be overwritten by the result
           of a realloc.
* @param size The current size of the array. Overwritten in case of success.
* @param newElem The element to be appended. The memory is reset upon success.
* @param type The datatype of the array members
* @return Returns UA_STATUSCODE_GOOD or UA_STATUSCODE_BADOUTOFMEMORY. The
           original array is left untouched in the failure case. */
UA_StatusCode
UA_Array_append(void **p, size_t *size, void *newElem,
               const UA_DataType *type);
/* Append a copy of the given element at the end of the array.
* @param p Double pointer to the array memory. Can be overwritten by the result
           of a realloc.
* @param size The current size of the array. Overwritten in case of success.
* @param newElem The element to be appended.
* @param type The datatype of the array members
* @return Returns UA_STATUSCODE_GOOD or UA_STATUSCODE_BADOUTOFMEMORY. The
          original array is left untouched in the failure case. */
```

5.7 Generated Data Type Definitions

The OPC UA standard defines many data types that are combinations of the 25 builtin data types. See the section on *Generated Definitions* for the list of data types that are integrated for this build of the open62541 library.

```
/* Helper used to exclude type names in the definition of UA_DataType structures
  * if the feature is disabled. */
#ifdef UA_ENABLE_TYPEDESCRIPTION
# define UA_TYPENAME(name) name,
#else
# define UA_TYPENAME(name)
#endif

#include <open62541/types_generated.h>
#include <open62541/types_generated_handling.h>
```

CHAPTER

SIX

SERVICES

In OPC UA, all communication is based on service calls, each consisting of a request and a response message. These messages are defined as data structures with a binary encoding and listed in *Generated Data Type Definitions*. Since all Services are pre-defined in the standard, they cannot be modified by the user. But you can use the *Call* service to invoke user-defined methods on the server.

The following service signatures are internal and *not visible to users*. Still, we present them here for an overview of the capabilities of OPC UA. Please refer to the *Client* and *Server* API where the services are exposed to end users. Please see part 4 of the OPC UA standard for the authoritative definition of the service and their behaviour.

Most services take as input the server, the current session and pointers to the request and response structures. Possible error codes are returned as part of the response.

```
typedef void (*UA_Service)(UA_Server*, UA_Session*,
                           const void *request, void *response);
typedef void (*UA_ChannelService)(UA_Server*, UA_SecureChannel*,
                                  const void *request, void *response);
typedef struct {
    UA_UInt32 requestTypeId;
#ifdef UA_ENABLE_DIAGNOSTICS
    UA_UInt16 counterOffset;
#endif
    UA_Boolean sessionRequired;
    UA_Service serviceCallback;
    const UA_DataType *requestType;
    const UA_DataType *responseType;
} UA_ServiceDescription;
/* Returns NULL if none found */
UA_ServiceDescription * getServiceDescription(UA_UInt32 requestTypeId);
```

6.1 Discovery Service Set

This Service Set defines Services used to discover the Endpoints implemented by a Server and to read the security configuration for those Endpoints.

6.1.1 FindServers Service

Returns the Servers known to a Server or Discovery Server. The Client may reduce the number of results returned by specifying filter criteria

6.1.2 GetEndpoints Service

Returns the Endpoints supported by a Server and all of the configuration information required to establish a SecureChannel and a Session.

6.1.3 FindServersOnNetwork Service

Returns the Servers known to a Discovery Server. Unlike FindServer, this Service is only implemented by Discovery Servers. It additionally returns servers which may have been detected through Multicast.

6.1.4 RegisterServer

Registers a remote server in the local discovery service.

6.1.5 RegisterServer2

This Service allows a Server to register its DiscoveryUrls and capabilities with a Discovery Server. It extends the registration information from RegisterServer with information necessary for FindServersOnNetwork.

6.2 SecureChannel Service Set

This Service Set defines Services used to open a communication channel that ensures the confidentiality and Integrity of all Messages exchanged with the Server.

6.2.1 OpenSecureChannel Service

Open or renew a SecureChannel that can be used to ensure Confidentiality and Integrity for Message exchange during a Session.

6.2.2 CloseSecureChannel Service

Used to terminate a SecureChannel.

```
void Service_CloseSecureChannel(UA_Server *server, UA_SecureChannel *channel);
```

6.3 Session Service Set

This Service Set defines Services for an application layer connection establishment in the context of a Session.

6.3.1 CreateSession Service

Used by an OPC UA Client to create a Session and the Server returns two values which uniquely identify the Session. The first value is the sessionId which is used to identify the Session in the audit logs and in the Server's address space. The second is the authenticationToken which is used to associate an incoming request with a Session.

6.3.2 ActivateSession

Used by the Client to submit its SoftwareCertificates to the Server for validation and to specify the identity of the user associated with the Session. This Service request shall be issued by the Client before it issues any other Service request after CreateSession. Failure to do so shall cause the Server to close the Session.

6.3.3 CloseSession

Used to terminate a Session.

6.3.4 Cancel Service

Used to cancel outstanding Service requests. Successfully cancelled service requests shall respond with Bad_RequestCancelledByClient.

6.4 NodeManagement Service Set

This Service Set defines Services to add and delete AddressSpace Nodes and References between them. All added Nodes continue to exist in the AddressSpace even if the Client that created them disconnects from the Server.

6.4.1 AddNodes Service

Used to add one or more Nodes into the AddressSpace hierarchy. If the type or one of the supertypes has any HasInterface references (see OPC 10001-7 - Amendment 7, 4.9.2), the child nodes of the interfaces are added to the new object.

6.4.2 AddReferences Service

Used to add one or more References to one or more Nodes.*/

6.4.3 DeleteNodes Service

Used to delete one or more Nodes from the AddressSpace.

6.4.4 DeleteReferences

Used to delete one or more References of a Node.

6.5 View Service Set

Clients use the browse Services of the View Service Set to navigate through the AddressSpace or through a View which is a subset of the AddressSpace.

6.5.1 Browse Service

Used to discover the References of a specified Node. The browse can be further limited by the use of a View. This Browse Service also supports a primitive filtering capability.

6.5.2 BrowseNext Service

Used to request the next set of Browse or BrowseNext response information that is too large to be sent in a single response. "Too large" in this context means that the Server is not able to return a larger response or that the number of results to return exceeds the maximum number of results to return that was specified by the Client in the original Browse request.

6.5.3 TranslateBrowsePathsToNodeIds Service

Used to translate textual node paths to their respective ids.

6.5.4 RegisterNodes Service

Used by Clients to register the Nodes that they know they will access repeatedly (e.g. Write, Call). It allows Servers to set up anything needed so that the access operations will be more efficient.

6.5.5 UnregisterNodes Service

This Service is used to unregister Nodelds that have been obtained via the RegisterNodes service.

6.6 Query Service Set

This Service Set is used to issue a Query to a Server. OPC UA Query is generic in that it provides an underlying storage mechanism independent Query capability that can be used to access a wide variety of OPC UA data stores and information management systems. OPC UA Query permits a Client to access data maintained by a Server without any knowledge of the logical schema used for internal storage of the data. Knowledge of the AddressSpace is sufficient.

6.6.1 QueryFirst Service

This Service is used to issue a Query request to the Server.

```
/* Not Implemented */
```

6.6.2 QueryNext Service

This Service is used to request the next set of QueryFirst or QueryNext response information that is too large to be sent in a single response.

```
/* Not Impelemented */
```

6.7 Attribute Service Set

This Service Set provides Services to access Attributes that are part of Nodes.

6.7.1 Read Service

Used to read attributes of nodes. For constructed attribute values whose elements are indexed, such as an array, this Service allows Clients to read the entire set of indexed values as a composite, to read individual elements or to read ranges of elements of the composite.

6.7.2 Write Service

Used to write attributes of nodes. For constructed attribute values whose elements are indexed, such as an array, this Service allows Clients to write the entire set of indexed values as a composite, to write individual elements or to write ranges of elements of the composite.

6.7.3 HistoryRead Service

Used to read historical values or Events of one or more Nodes. Servers may make historical values available to Clients using this Service, although the historical values themselves are not visible in the AddressSpace.

6.7.4 HistoryUpdate Service

Used to update historical values or Events of one or more Nodes. Several request parameters indicate how the Server is to update the historical value or Event. Valid actions are Insert, Replace or Delete.

6.8 Method Service Set

The Method Service Set defines the means to invoke methods. A method shall be a component of an Object. See the section on *MethodNodes* for more information.

6.8.1 Call Service

Used to call (invoke) a methods. Each method call is invoked within the context of an existing Session. If the Session is terminated, the results of the method's execution cannot be returned to the Client and are discarded.

6.9 MonitoredItem Service Set

Clients define MonitoredItems to subscribe to data and Events. Each MonitoredItem identifies the item to be monitored and the Subscription to use to send Notifications. The item to be monitored may be any Node Attribute.

6.9.1 CreateMonitoredItems Service

Used to create and add one or more MonitoredItems to a Subscription. A MonitoredItem is deleted automatically by the Server when the Subscription is deleted. Deleting a MonitoredItem causes its entire set of triggered item links to be deleted, but has no effect on the MonitoredItems referenced by the triggered items.

6.9.2 DeleteMonitoredItems Service

Used to remove one or more MonitoredItems of a Subscription. When a MonitoredItem is deleted, its triggered item links are also deleted.

6.9.3 ModifyMonitoredItems Service

Used to modify MonitoredItems of a Subscription. Changes to the MonitoredItem settings shall be applied immediately by the Server. They take effect as soon as practical but not later than twice the new revisedSamplingInterval.

Illegal request values for parameters that can be revised do not generate errors. Instead the server will choose default values and indicate them in the corresponding revised parameter.

6.9.4 SetMonitoringMode Service

Used to set the monitoring mode for one or more MonitoredItems of a Subscription.

6.9.5 SetTriggering Service

Used to create and delete triggering links for a triggering item.

6.10 Subscription Service Set

Subscriptions are used to report Notifications to the Client.

6.10.1 CreateSubscription Service

Used to create a Subscription. Subscriptions monitor a set of MonitoredItems for Notifications and return them to the Client in response to Publish requests.

6.10.2 ModifySubscription Service

Used to modify a Subscription.

6.10.3 SetPublishingMode Service

Used to enable sending of Notifications on one or more Subscriptions.

6.10.4 Publish Service

Used for two purposes. First, it is used to acknowledge the receipt of NotificationMessages for one or more Subscriptions. Second, it is used to request the Server to return a NotificationMessage or a keep-alive Message.

Note that the service signature is an exception and does not contain a pointer to a PublishResponse. That is because the service queues up publish requests internally and sends responses asynchronously based on timeouts.

Also, this is the only service method that returns a StatusCode. This simplifies keeping track of the diagnostics statistics.

6.10.5 Republish Service

Requests the Subscription to republish a NotificationMessage from its retransmission queue.

6.10.6 DeleteSubscriptions Service

Invoked to delete one or more Subscriptions that belong to the Client's Session.

6.10.7 TransferSubscription Service

Used to transfer a Subscription and its MonitoredItems from one Session to another. For example, a Client may need to reopen a Session and then transfer its Subscriptions to that Session. It may also be used by one Client to take over a Subscription from another Client by transferring the Subscription to its Session.

CHAPTER

SEVEN

SERVER

7.1 Server Configuration

The configuration structure is passed to the server during initialization. The server expects that the configuration is not modified during runtime. Currently, only one server can use a configuration at a time. During shutdown, the server will clean up the parts of the configuration that are modified at runtime through the provided API.

Examples for configurations are provided in the /plugins folder. The usual usage is as follows:

- 1. Create a server configuration with default settings as a starting point
- 2. Modifiy the configuration, e.g. by adding a server certificate
- 3. Instantiate a server with it
- 4. After shutdown of the server, clean up the configuration (free memory)

The *Tutorials* provide a good starting point for this.

7.1.1 Server Description

The description must be internally consistent. The ApplicationUri set in the ApplicationDescription must match the URI set in the server certificate. The applicationType is not just descriptive, it changes the actual functionality of the server. The RegisterServer service is available only if the server is a DiscoveryServer and the applicationType is set to the appropriate value.*/

7.1.2 Server Lifecycle

```
/* Delay in ms from the shutdown signal (ctrl-c) until the actual shutdown.
  * Clients need to be able to get a notification ahead of time. */
UA_Double shutdownDelay;

/* If an asynchronous server shutdown is used, this callback notifies about
  * the current lifecycle state (notably the STOPPING -> STOPPED
  * transition). */
void (*notifyLifecycleState)(UA_Server *server, UA_LifecycleState state);
```

7.1.3 Rule Handling

Override the handling of standard-defined behavior. These settings are used to balance the following contradicting requirements:

- Strict conformance with the standard (for certification).
- Ensure interoperability with old/non-conforming implementations encountered in the wild.

The defaults are set for compatibility with the largest number of OPC UA vendors (with log warnings activated). Cf. Postel's Law "be conservative in what you send, be liberal in what you accept".

See the section Rule Handling for the possible settings.

```
/* Verify that the server sends a timestamp in the request header */
UA_RuleHandling verifyRequestTimestamp;

/* Variables (that don't have a DataType of BaseDataType) must not have an
  * empty variant value. The default behaviour is to auto-create a matching
  * zeroed-out value for empty VariableNodes when they are added. */
UA_RuleHandling allowEmptyVariables;
```

7.1.4 Custom Data Types

The following is a linked list of arrays with custom data types. All data types that are accessible from here are automatically considered for the decoding of received messages. Custom data types are not cleaned up together with the configuration. So it is possible to allocate them on ROM.

See the section on *Generic Type Handling*. Examples for working with custom data types are provided in /examples/custom_datatype/.

```
const UA_DataTypeArray *customDataTypes;
```

Note: See the section on *Generic Type Handling*. Examples for working with custom data types are provided in /examples/custom_datatype/.

7.1.5 EventLoop

The sever can be plugged into an external EventLoop. Otherwise the EventLoop is considered to be attached to the server's lifecycle and will be destroyed when the config is cleaned up.

```
UA_EventLoop *eventLoop;
UA_Boolean externalEventLoop; /* The EventLoop is not deleted with the config */
```

7.1.6 Networking

The severUrls array contains the server URLs like opc.tcp://my-server:4840 or opc.wss://localhost:443. The URLs are used both for discovery and to set up the server sockets based on the defined hostnames (and ports).

- If the list is empty: Listen on all network interfaces with TCP port 4840.
- If the hostname of a URL is empty: Use the define protocol and port and listen on all interfaces.

```
UA_String *serverUrls;
size_t serverUrlsSize;
```

The following settings are specific to OPC UA with TCP transport.

7.1.7 Security and Encryption

```
size_t securityPoliciesSize;
UA_SecurityPolicy* securityPolicies;

/* Endpoints with combinations of SecurityPolicy and SecurityMode. If the
   * UserIdentityToken array of the Endpoint is not set, then it will be
   * filled by the server for all UserTokenPolicies that are configured in the
   * AccessControl plugin. */
size_t endpointsSize;
UA_EndpointDescription *endpoints;

/* Only allow the following discovery services to be executed on a
   * SecureChannel with SecurityPolicyNone: GetEndpointsRequest,
   * FindServersRequest and FindServersOnNetworkRequest.
   *
   * Only enable this option if there is no endpoint with SecurityPolicy#None
   * in the endpoints list. The SecurityPolicy#None must be present in the
   * securityPolicies list. */
```

```
UA_Boolean securityPolicyNoneDiscoveryOnly;

/* Allow clients without encryption support to connect with username and password.

* This requires to transmit the password in plain text over the network which is

* why this option is disabled by default.

* Make sure you really need this before enabling plain text passwords. */

UA_Boolean allowNonePolicyPassword;

/* Different sets of certificates are trusted for SecureChannel / Session */

UA_CertificateVerification secureChannelPKI;

UA_CertificateVerification sessionPKI;
```

See the section for access-control handling.

```
UA_AccessControl accessControl;
```

7.1.8 Nodes and Node Lifecycle

See the section for *node lifecycle handling*.

```
UA_Nodestore nodestore;
UA_GlobalNodeLifecycle nodeLifecycle;
```

Copy the HasModellingRule reference in instances from the type definition in UA_Server_addObjectNode and UA_Server_addVariableNode.

Part 3 - 6.4.4: [...] it is not required that newly created or referenced instances based on InstanceDeclarations have a ModellingRule, however, it is allowed that they have any ModellingRule independent of the ModellingRule of their InstanceDeclaration

```
UA_Boolean modellingRulesOnInstances;
```

7.1.9 Limits

```
/* Limits for SecureChannels */
UA_UInt16 maxSecureChannels;
UA_UInt32 maxSecurityTokenLifetime; /* in ms */

/* Limits for Sessions */
UA_UInt16 maxSessions;
UA_Double maxSessionTimeout; /* in ms */

/* Operation limits */
UA_UInt32 maxNodesPerRead;
UA_UInt32 maxNodesPerWrite;
UA_UInt32 maxNodesPerMethodCall;
UA_UInt32 maxNodesPerBrowse;
UA_UInt32 maxNodesPerBrowse;
UA_UInt32 maxNodesPerRegisterNodes;
```

```
UA_UInt32 maxNodesPerTranslateBrowsePathsToNodeIds;
UA_UInt32 maxNodesPerNodeManagement;
UA_UInt32 maxMonitoredItemsPerCall;

/* Limits for Requests */
UA_UInt32 maxReferencesPerNode;
```

7.1.10 Async Operations

See the section for async operations.

```
#if UA_MULTITHREADING >= 100
    UA_Double asyncOperationTimeout; /* in ms, 0 => unlimited */
    size_t maxAsyncOperationQueueSize; /* 0 => unlimited */
    /* Notify workers when an async operation was enqueued */
    UA_Server_AsyncOperationNotifyCallback asyncOperationNotifyCallback;
#endif
```

7.1.11 Discovery

```
#ifdef UA_ENABLE_DISCOVERY
   /* Timeout in seconds when to automatically remove a registered server from
    * the list, if it doesn't re-register within the given time frame. A value
    * of 0 disables automatic removal. Default is 60 Minutes (60*60). Must be
    * bigger than 10 seconds, because cleanup is only triggered approximately
    * every 10 seconds. The server will still be removed depending on the
    * state of the semaphore file. */
    UA_UInt32 discoveryCleanupTimeout;
# ifdef UA_ENABLE_DISCOVERY_MULTICAST
    UA_Boolean mdnsEnabled;

* @param server The server object.
* @param waitInternal Should we wait for messages in the networklayer?
         Otherwise, the timeouts for the networklayers are set to zero.
          The default max wait time is 200ms.
\star @return Returns how long we can wait until the next scheduled
          callback (in ms) */
UA_UInt16
UA_Server_run_iterate(UA_Server *server, UA_Boolean waitInternal);
```

```
/* The epilogue part of UA_Server_run (no need to use if you call
  * UA_Server_run or UA_Server_runUntilInterrupt) */
UA_StatusCode
UA_Server_run_shutdown(UA_Server *server);
```

7.3 Timed Callbacks

Add a callback to the server that is executed at a defined time. The callback can also be registered with a cyclic interval.

```
/* Add a callback for execution at a specified time. If the indicated time lies
* in the past, then the callback is executed at the next iteration of the
* server's main loop.
* @param server The server object.
* @param callback The callback that shall be added.
* @param data Data that is forwarded to the callback.
* @param date The timestamp for the execution time.
\star @param callbackId Set to the identifier of the repeated callback . This can
         be used to cancel the callback later on. If the pointer is null, the
          identifier is not set.
* @return Upon success, ``UA_STATUSCODE_GOOD`` is returned. An error code
          otherwise. */
UA_StatusCode UA_THREADSAFE
UA_Server_addTimedCallback(UA_Server *server, UA_ServerCallback callback,
                           void *data, UA_DateTime date, UA_UInt64 *callbackId);
/* Add a callback for cyclic repetition to the server.
* @param server The server object.
* @param callback The callback that shall be added.
* @param data Data that is forwarded to the callback.
* @param interval_ms The callback shall be repeatedly executed with the given
         interval (in ms). The interval must be positive. The first execution
          occurs at now() + interval at the latest.
* @param callbackId Set to the identifier of the repeated callback . This can
         be used to cancel the callback later on. If the pointer is null, the
         identifier is not set.
* @return Upon success, ``UA_STATUSCODE_GOOD`` is returned. An error code
          otherwise. */
UA_StatusCode UA_THREADSAFE
UA_Server_addRepeatedCallback(UA_Server *server, UA_ServerCallback callback,
                              void *data, UA_Double interval_ms,
                              UA_UInt64 *callbackId);
UA_StatusCode UA_THREADSAFE
UA_Server_changeRepeatedCallbackInterval(UA_Server *server, UA_UInt64 callbackId,
                                         UA_Double interval_ms);
```

7.4 Session Handling

A new session is announced via the AccessControl plugin. The session identifier is forwarded to the relevant callbacks back into userland. The following methods enable an interaction with a particular session.

```
/* Manually close a session */
UA_StatusCode UA_THREADSAFE
UA_Server_closeSession(UA_Server *server, const UA_NodeId *sessionId);
```

Session attributes: Besides the user-definable session context pointer (set by the AccessControl plugin when the Session is created), a session carries attributes in a key-value list. Some attributes are present in every session and shown in the list below. Additional attributes can be manually set as meta-data.

Always present as session attributes are:

- 0:localeIds [UA_String]: List of preferred languages (read-only)
- 0:clientDescription [UA_ApplicationDescription]: Client description (read-only)
- 0:sessionName [String] Client-defined name of the session (read-only)
- 0:clientUserId [String] User identifier used to activate the session (read-only)

```
* right datatype. Otherwise a shallow copy of the scalar value is created at
* the target location of the void pointer. Hence don't use this in a
* multi-threaded application. */
UA_StatusCode
UA_Server_getSessionAttribute_scalar(UA_Server *server,
                                     const UA_NodeId *sessionId,
                                     const UA_QualifiedName key,
                                     const UA_DataType *type,
                                     void *outValue);
UA_StatusCode UA_THREADSAFE
UA_Server_setSessionAttribute(UA_Server *server, const UA_NodeId *sessionId,
                              const UA_QualifiedName key,
                              const UA_Variant *value);
UA_StatusCode UA_THREADSAFE
UA_Server_deleteSessionAttribute(UA_Server *server, const UA_NodeId *sessionId,
                                 const UA_QualifiedName key);
```

7.5 Reading and Writing Node Attributes

The functions for reading and writing node attributes call the regular read and write service in the background that are also used over the network.

The following attributes cannot be read, since the local "admin" user always has full rights.

- UserWriteMask
- UserAccessLevel
- UserExecutable

```
/* Read an attribute of a node. The specialized functions below provide a more
* concise syntax.
* @param server The server object.
* @param item ReadValueIds contain the NodeId of the target node, the id of the
              attribute to read and (optionally) an index range to read parts
              of an array only. See the section on NumericRange for the format
               used for array ranges.
* @param timestamps Which timestamps to return for the attribute.
* @return Returns a DataValue that contains either an error code, or a variant
          with the attribute value and the timestamps. */
UA_DataValue UA_THREADSAFE
UA_Server_read(UA_Server *server, const UA_ReadValueId *item,
               UA_TimestampsToReturn timestamps);
/* Don't use this function. There are typed versions for every supported
* attribute. */

/* Set the callback which is called if another server is found through mDNS or
* deleted. It will be called for any mDNS message from the remote server, thus
* it may be called multiple times for the same instance. Also the SRV and TXT
* records may arrive later, therefore for the first call the server
* capabilities may not be set yet. If called multiple times, previous data will
* be overwritten.
* @param server
* @param cb the callback
* @param data data passed to the callback
 * @return ``UA_STATUSCODE_SUCCESS`` on success */
```

7.8 Information Model Callbacks

There are three places where a callback from an information model to user-defined code can happen.

- Custom node constructors and destructors
- Linking VariableNodes with an external data source
- MethodNode callbacks

7.8.1 Data Source Callback

The server has a unique way of dealing with the content of variables. Instead of storing a variant attached to the variable node, the node can point to a function with a local data provider. Whenever the value attribute is read, the function will be called and asked to provide a UA_DataValue return value that contains the value content and additional timestamps.

It is expected that the read callback is implemented. The write callback can be set to a null-pointer.

```
UA_StatusCode UA_THREADSAFE
UA_Server_setVariableNode_dataSource(UA_Server *server, const UA_NodeId nodeId, const UA_DataSource dataSource);

(continues on next page)
```

7.8.2 Local MonitoredItems

MonitoredItems are used with the Subscription mechanism of OPC UA to transported notifications for data changes and events. MonitoredItems can also be registered locally. Notifications are then forwarded to a user-defined callback instead of a remote client.

```
#ifdef UA_ENABLE_SUBSCRIPTIONS
typedef void (*UA_Server_DataChangeNotificationCallback)
    (UA_Server *server, UA_UInt32 monitoredItemId, void *monitoredItemContext,
    const UA_NodeId *nodeId, void *nodeContext, UA_UInt32 attributeId,
    const UA_DataValue *value);
typedef void (*UA_Server_EventNotificationCallback)
    (UA_Server *server, UA_UInt32 monId, void *monContext,
     size_t nEventFields, const UA_Variant *eventFields);
/* Create a local MonitoredItem with a sampling interval that detects data
* changes.
*
* @param server The server executing the MonitoredItem
* @timestampsToReturn Shall timestamps be added to the value for the callback?
* @item The parameters of the new MonitoredItem. Note that the attribute of the
         ReadValueId (the node that is monitored) can not be
         ``UA_ATTRIBUTEID_EVENTNOTIFIER``. A different callback type needs to be
         registered for event notifications.
* @monitoredItemContext A pointer that is forwarded with the callback
* @callback The callback that is executed on detected data changes
* @return Returns a description of the created MonitoredItem. The structure
* also contains a StatusCode (in case of an error) and the identifier of the
* new MonitoredItem. */
UA_MonitoredItemCreateResult UA_THREADSAFE
UA_Server_createDataChangeMonitoredItem(UA_Server *server,
          UA_TimestampsToReturn timestampsToReturn,
          const UA_MonitoredItemCreateRequest item,
          void *monitoredItemContext,
          UA_Server_DataChangeNotificationCallback callback);
```

```
/* UA_MonitoredItemCreateResult */
/* UA_Server_createEventMonitoredItem(UA_Server *server, */
/* UA_TimestampsToReturn timestampsToReturn, */
/* const UA_MonitoredItemCreateRequest item, void *context, */
/* UA_Server_EventNotificationCallback callback); */

UA_StatusCode UA_THREADSAFE
UA_Server_deleteMonitoredItem(UA_Server *server, UA_UInt32 monitoredItemId);
#endif
#endif
```

7.8.3 Method Callbacks

Method callbacks are set to *NULL* (not executable) when a method node is added over the network. In theory, it is possible to add a callback via UA_Server_setMethodNode_callback within the global constructor when adding methods over the network is really wanted. See the Section *Interacting with Objects* for calling methods on an object.

7.9 Interacting with Objects

Objects in the information model are represented as ObjectNodes. Some convenience functions are provided to simplify the interaction with objects.

```
* @param server The server object
* @param objectId The identifier of the object (node)
* @param propertyName The name of the property
* @param value The value to be set for the event attribute
* @return The StatusCode for setting the event attribute */
UA_StatusCode UA_THREADSAFE
UA_Server_writeObjectProperty(UA_Server *server, const UA_NodeId objectId,
                              const UA_QualifiedName propertyName,
                              const UA_Variant value);
/* Directly point to the scalar value instead of a variant */
UA_StatusCode UA_THREADSAFE
UA_Server_writeObjectProperty_scalar(UA_Server *server, const UA_NodeId objectId,
                                     const UA_QualifiedName propertyName,
                                     const void *value, const UA_DataType *type);
/* Read an object property.
* @param server The server object
* @param objectId The identifier of the object (node)
* @param propertyName The name of the property
* @param value Contains the property value after reading. Must not be NULL.
* @return The StatusCode for setting the event attribute */
UA_StatusCode UA_THREADSAFE
UA_Server_readObjectProperty(UA_Server *server, const UA_NodeId objectId,
                             const UA_QualifiedName propertyName,
                             UA_Variant *value);
```

7.10 Node Addition and Deletion

When creating dynamic node instances at runtime, chances are that you will not care about the specific Nodeld of the new node, as long as you can reference it later. When passing numeric Nodelds with a numeric identifier 0, the stack evaluates this as "select a random unassigned numeric Nodeld in that namespace". To find out which Nodeld was actually assigned to the new node, you may pass a pointer *outNewNodeld*, which will (after a successful node insertion) contain the nodeld of the new node. You may also pass a NULL pointer if this result is not needed.

See the Section *Node Lifecycle: Constructors, Destructors and Node Contexts* on constructors and on attaching user-defined data to nodes.

The Section default-node-attributes contains useful starting points for defining node attributes. Forgetting to set the ValueRank or the AccessLevel leads to errors that can be hard to track down for new users. The default attributes have a high likelihood to "do the right thing".

The methods for node addition and deletion take mostly const arguments that are not modified. When creating a node, a deep copy of the node identifier, node attributes, etc. is created. Therefore, it is possible to call for example UA_Server_addVariablenode with a value attribute (a Variant) pointing to a memory location on the stack. If you need changes to a variable value to manifest at a specific memory location, please use a Data Source Callback or a Value Callback.

#endif
```

The method pair UA_Server_addNode_begin and _finish splits the AddNodes service in two parts. This is useful if the node shall be modified before finish the instantiation. For example to add children with specific Nodelds. Otherwise, mandatory children (e.g. of an ObjectType) are added with pseudorandom unique Nodelds. Existing children are detected during the _finish part via their matching BrowseName.

The _begin method:

- prepares the node and adds it to the nodestore
- copies some unassigned attributes from the TypeDefinition node internally
- adds the references to the parent (and the TypeDefinition if applicable)
- performs type-checking of variables.

You can add an object node without a parent if you set the parentNodeId and referenceTypeId to UA_NODE_ID_NULL. Then you need to add the parent reference and hasTypeDef reference yourself before calling the _finish method. Not that this is only allowed for object nodes.

The _finish method:

- · copies mandatory children
- calls the node constructor(s) at the end

• may remove the node if it encounters an error.

The special UA_Server_addMethodNode_finish method needs to be used for method nodes, since there you need to explicitly specifiy the input and output arguments which are added in the finish step (if not yet already there)

```
/* The ``attr`` argument must have a type according to the NodeClass.
* ``VariableAttributes`` for variables, ``ObjectAttributes`` for objects, and
* so on. Missing attributes are taken from the TypeDefinition node if
* applicable. */

7.11 Reference Management

```
const UA_NodeId referenceTypeId, UA_Boolean isForward,
const UA_ExpandedNodeId targetNodeId,
UA_Boolean deleteBidirectional);
```

7.12 Events

The method UA_Server_createEvent creates an event and represents it as node. The node receives a unique *EventId* which is automatically added to the node. The method returns a *NodeId* to the object node which represents the event through outNodeId. The *NodeId* can be used to set the attributes of the event. The generated *NodeId* is always numeric. outNodeId cannot be NULL.

Note: In order to see an event in UAExpert, the field *Time* must be given a value!

The method UA_Server_triggerEvent "triggers" an event by adding it to all monitored items of the specified origin node and those of all its parents. Any filters specified by the monitored items are automatically applied. Using this method deletes the node generated by UA_Server_createEvent. The *EventId* for the new event is generated automatically and is returned through outEventId. NULL can be passed if the *EventId* is not needed. deleteEventNode specifies whether the node representation of the event should be deleted after invoking the method. This can be useful if events with the similar attributes are triggered frequently. UA_TRUE would cause the node to be deleted.

```
#ifdef UA_ENABLE_SUBSCRIPTIONS_EVENTS
/* Creates a node representation of an event

7.14 Update the Server Certificate at Runtime

7.15 Utility Functions

7.16 Async Operations

Some operations (such as reading out a sensor that needs to warm up) can take quite some time. In order not to block the server during such an operation, it can be "outsourced" to a worker thread.

Take the example of a CallRequest. It is split into the individual method call operations. If the method is marked as async, then the operation is put into a queue where it is be retrieved by a worker. The worker returns the result when ready. See the examples in /examples/tutorial_server_method_async.c for the usage.

Note that the operation can time out (see the asyncOperationTimeout setting in the server config) also when it has been retrieved by the worker.

```
#if UA_MULTITHREADING >= 100
/* Set the async flag in a method node */
UA_StatusCode
UA_Server_setMethodNodeAsync(UA_Server *server, const UA_NodeId id,
                             UA_Boolean isAsync);

```

7.17 Statistics

Statistic counters keeping track of the current state of the stack. Counters are structured per OPC UA communication layer.

```
typedef struct {
    UA_SecureChannelStatistics scs;
    UA_SessionStatistics ss;
} UA_ServerStatistics;

UA_ServerStatistics
UA_Server_getStatistics(UA_Server *server);
```

7.18 Reverse Connect

The reverse connect feature of OPC UA permits the server instead of the client to establish the connection. The client must expose the listening port so the server is able to reach it.

```
/* The reverse connect state change callback is called whenever the state of a
 * reverse connect is changed by a connection attempt, a successful connection
 * or a connection loss.
 *
 * The reverse connect states reflect the state of the secure channel currently
 * associated with a reverse connect. The state will remain
```

```
* UA_SECURECHANNELSTATE_CONNECTING while the server attempts repeatedly to
* establish a connection. */
typedef void (*UA_Server_ReverseConnectStateCallback)(UA_Server *server,
                                                      UA_UInt64 handle,
                                                      UA_SecureChannelState state,
                                                      void *context);
/* Registers a reverse connect in the server. The server periodically attempts
* to establish a connection if the initial connect fails or if the connection
* breaks.
* @param server The server object
* @param url The URL of the remote client
* @param stateCallback The callback which will be called on state changes
* @param callbackContext The context for the state callback
* @param handle Is set to the handle of the reverse connect if not NULL
* @return Returns UA_STATUSCODE_GOOD if the reverse connect has been registered */
UA_StatusCode
UA_Server_addReverseConnect(UA_Server *server, UA_String url,
                            UA_Server_ReverseConnectStateCallback stateCallback,
                            void *callbackContext, UA_UInt64 *handle);
/* Removes a reverse connect from the server and closes the connection if it is
* currently open.
* @param server The server object
* @param handle The handle of the reverse connect to remove
* @return Returns UA_STATUSCODE_GOOD if the reverse connect has been
          successfully removed */
UA_StatusCode
UA_Server_removeReverseConnect(UA_Server *server, UA_UInt64 handle);
```

CHAPTER

EIGHT

CLIENT

The client implementation allows remote access to all OPC UA services. For convenience, some functionality has been wrapped in *high-level abstractions*.

However: At this time, the client does not yet contain its own thread or event-driven main-loop, meaning that the client will not perform any actions automatically in the background. This is especially relevant for connection/session management and subscriptions. The user will have to periodically call *UA_Client_run_iterate* to ensure that asynchronous events are handled, including keeping a secure connection established. See more about *asynchronicity* and *subscriptions*.

8.1 Client Configuration

The client configuration is used for setting connection parameters and additional settings used by the client. The configuration should not be modified after it is passed to a client. Currently, only one client can use a configuration at a time.

Examples for configurations are provided in the /plugins folder. The usual usage is as follows:

- 1. Create a client configuration with default settings as a starting point
- 2. Modifiy the configuration, e.g. modifying the timeout
- 3. Instantiate a client with it
- 4. After shutdown of the client, clean up the configuration (free memory)

The *Tutorials* provide a good starting point for this.

```
/* The endpoint for the client to connect to.
  * Such as "opc.tcp://host:port". */
UA_String endpointUrl;
```

8.1.1 Connection configuration

The following configuration elements reduce the "degrees of freedom" the client has when connecting to a server. If no connection can be made under these restrictions, then the connection will abort with an error message.

If either endpoint or userTokenPolicy has been set (at least one non-zero byte in either structure), then the selected Endpoint and UserTokenPolicy overwrite the settings in the basic connection configuration. The userTokenPolicy array in the EndpointDescription is ignored. The selected userTokenPolicy is set in the dedicated configuration field.

If the advanced configuration is not set, the client will write to it the selected Endpoint and UserTokenPolicy during GetEndpoints.

The information in the advanced configuration is used during reconnect when the SecureChannel was broken.

```
UA_EndpointDescription endpoint;
UA_UserTokenPolicy userTokenPolicy;
```

If the EndpointDescription has not been defined, the ApplicationURI constrains the servers considered in the FindServers service and the Endpoints considered in the GetEndpoints service.

If empty the application URI is not used to filter.

```
UA_String applicationUri;
```

8.1.2 Custom Data Types

The following is a linked list of arrays with custom data types. All data types that are accessible from here are automatically considered for the decoding of received messages. Custom data types are not cleaned up together with the configuration. So it is possible to allocate them on ROM.

See the section on *Generic Type Handling*. Examples for working with custom data types are provided in /examples/custom_datatype/.

```
const UA_DataTypeArray *customDataTypes;
```

8.1.3 Advanced Client Configuration

```
UA_UInt32 secureChannelLifeTime; /* Lifetime in ms (then the channel needs
                                       to be renewed) */
   UA_UInt32 requestedSessionTimeout; /* Session timeout in ms */
   UA_ConnectionConfig localConnectionConfig;
   UA_UInt32 connectivityCheckInterval;
                                           /* Connectivity check interval in ms.
                                             * 0 = background task disabled */
   /* EventLoop */
   UA_EventLoop *eventLoop;
   UA_Boolean externalEventLoop; /* The EventLoop is not deleted with the config */
   /* Available SecurityPolicies */
   size_t securityPoliciesSize;
   UA_SecurityPolicy *securityPolicies;
   /* Certificate Verification Plugin */
   UA_CertificateVerification certificateVerification;
   /* Available SecurityPolicies for Authentication. The policy defined by the
    * AccessControl is selected. If no policy is defined, the policy of the secure_
∽channel
    * is selected.*/
   size_t authSecurityPoliciesSize;
   UA_SecurityPolicy *authSecurityPolicies;
   /* SecurityPolicyUri for the Authentication. */
   UA_String authSecurityPolicyUri;
   /* Callback for state changes. The client state is differentated into the
    * SecureChannel state and the Session state. The connectStatus is set if
    * the client connection (including reconnects) has failed and the client
    * has to "give up". If the connectStatus is not set, the client still has
    * hope to connect or recover. */
   void (*stateCallback)(UA_Client *client,
                         UA_SecureChannelState channelState,
                         UA_SessionState sessionState,
                         UA_StatusCode connectStatus);
```

```
/* When connectivityCheckInterval is greater than 0, every
    * connectivityCheckInterval (in ms), an async read request is performed on
    * the server. inactivityCallback is called when the client receive no
    * response for this read request The connection can be closed, this in an
     * attempt to recreate a healthy connection. */
    void (*inactivityCallback)(UA_Client *client);
    /* Number of PublishResponse queued up in the server */
   UA_UInt16 outStandingPublishRequests;
    /* If the client does not receive a PublishResponse after the defined delay
    * of ``(sub->publishingInterval * sub->maxKeepAliveCount) +
    * client->config.timeout) ``, then subscriptionInactivityCallback is called
    * for the subscription.. */
    void (*subscriptionInactivityCallback)(UA_Client *client,
                                           UA_UInt32 subscriptionId,
                                           void *subContext);
    /* Session config */
    UA_String sessionName;
    UA_LocaleId *sessionLocaleIds;
    size_t sessionLocaleIdsSize;
#ifdef UA_ENABLE_ENCRYPTION
    /* If the private key is in PEM format and password protected, this callback
    * is called during initialization to get the password to decrypt the
    * private key. The memory containing the password is freed by the client
    * after use. The callback should be set early, other parts of the client
    * config setup may depend on it. */
    UA_StatusCode (*privateKeyPasswordCallback)(UA_ClientConfig *cc,
                                                UA_ByteString *password);
#endif
};
```

@brief It makes a partial deep copy of the clientconfig. It makes a shallow copies of the plugins (logger, eventloop, securitypolicy).

NOTE: It makes a shallow copy of all the plugins from source to destination. Therefore calling _clear on the dst object will also delete the plugins in src object.

```
UA_StatusCode
UA_ClientConfig_copy(UA_ClientConfig const *src, UA_ClientConfig *dst);
```

@brief It cleans the client config and frees the pointer.

```
void
UA_ClientConfig_delete(UA_ClientConfig *config);
```

@brief It cleans the client config and deletes the plugins, whereas _copy makes a shallow copy of the plugins.

```
void
UA_ClientConfig_clear(UA_ClientConfig *config);
/* Configure Username/Password for the Session authentication. Also see
* UA_ClientConfig_setAuthenticationCert for x509-based authentication, which is
* implemented as a plugin (as it can be based on different crypto
* libraries). */
UA_INLINABLE( UA_StatusCode
UA_ClientConfig_setAuthenticationUsername(UA_ClientConfig *config,
                                          const char *username,
                                          const char *password) ,{
    UA_UserNameIdentityToken* identityToken = UA_UserNameIdentityToken_new();
    if(!identityToken)
        return UA_STATUSCODE_BADOUTOFMEMORY;
    identityToken->userName = UA_STRING_ALLOC(username);
    identityToken->password = UA_STRING_ALLOC(password);
    UA_ExtensionObject_clear(&config->userIdentityToken);
    UA_ExtensionObject_setValue(&config->userIdentityToken, identityToken,
                                &UA_TYPES[UA_TYPES_USERNAMEIDENTITYTOKEN]);
    return UA_STATUSCODE_GOOD;
})
```

8.2 Client Lifecycle

```
/* Create a new client with a default configuration that adds plugins for
* networking, security, logging and so on. See `client_config_default.h` for
* more detailed options.
* The default configuration can be used as the starting point to adjust the
* client configuration to individual needs. UA_Client_new is implemented in the
* /plugins folder under the CCO license. Furthermore the client confiugration
* only uses the public server API.
* @return Returns the configured client or NULL if an error occurs. */
UA_Client * UA_Client_new(void);
/* Creates a new client. Moves the config into the client with a shallow copy.
* The config content is cleared together with the client. */
UA_Client_newWithConfig(const UA_ClientConfig *config);
/* Returns the current state. All arguments except ``client`` can be NULL. */
void UA_THREADSAFE
UA_Client_getState(UA_Client *client,
                   UA_SecureChannelState *channelState,
                   UA_SessionState *sessionState,
                   UA_StatusCode *connectStatus);
```

```
/* Get the client configuration */
UA_ClientConfig *
UA_Client_getConfig(UA_Client *client);

/* Get the client context */
UA_INLINABLE( void *
UA_Client_getContext(UA_Client *client) ,{
    return UA_Client_getConfig(client)->clientContext; /* Cannot fail */
})

/* (Disconnect and) delete the client */
void
UA_Client_delete(UA_Client *client);
```

8.3 Connection Attributes

Besides the client configuration, some attributes of the connection are defined only at runtime. For example the choice of SecurityPolicy or the ApplicationDescripton from the server. This API allows to access such connection attributes.

The currently defined connection attributes are:

- 0:serverDescription [UA_ApplicationDescription]: Server description
- 0:securityPolicyUri [UA_String]: Uri of the SecurityPolicy used
- 0:securityMode [UA_MessageSecurityMode]: SecurityMode of the SecureChannel

```
/* Returns a shallow copy of the attribute. Don't _clear or _delete the value
* variant. Don't use the value after returning the control flow to the client.
* Also don't use this in a multi-threaded application. */
UA_StatusCode
UA_Client_getConnectionAttribute(UA_Client *client, const UA_QualifiedName key,
                                 UA_Variant *outValue);
/* Return a deep copy of the attribute */
UA_StatusCode UA_THREADSAFE
UA_Client_getConnectionAttributeCopy(UA_Client *client, const UA_QualifiedName key,
                                     UA_Variant *outValue);
/* Returns NULL if the attribute is not defined or not a scalar or not of the
* right datatype. Otherwise a shallow copy of the scalar value is created at
* the target location of the void pointer. Hence don't use this in a
* multi-threaded application. */
UA_StatusCode
UA_Client_getConnectionAttribute_scalar(UA_Client *client,
                                        const UA_QualifiedName key,
                                        const UA_DataType *type,
                                        void *outValue);
```

8.4 Connect to a Server

Once a client is connected to an endpointUrl, it is not possible to switch to another server. A new client has to be created for that.

Once a connection is established, the client keeps the connection open and reconnects if necessary.

If the connection fails unrecoverably (state->connectStatus is set to an error), the client is no longer usable. Create a new client if required.

```
/* Connect with the client configuration. For the async connection, finish
* connecting via UA_Client_run_iterate (or manually running a configured
* external EventLoop). */
UA_StatusCode UA_THREADSAFE
__UA_Client_connect(UA_Client *client, UA_Boolean async);
/* Connect to the server. First a SecureChannel is opened, then a Session. The
* client configuration restricts the SecureChannel selection and contains the
* UserIdentityToken for the Session.
* @param client to use
* @param endpointURL to connect (for example "opc.tcp://localhost:4840")
\star @return Indicates whether the operation succeeded or returns an error code \star/
UA_INLINABLE( UA_StatusCode
UA_Client_connect(UA_Client *client, const char *endpointUrl), {
    /* Update the configuration */
   UA_ClientConfig *cc = UA_Client_getConfig(client);
    cc->noSession = false; /* Open a Session */
   UA_String_clear(&cc->endpointUrl);
   cc->endpointUrl = UA_STRING_ALLOC(endpointUrl);
    /* Connect */
    return __UA_Client_connect(client, false);
})
/* Connect async (non-blocking) to the server. After initiating the connection,
* call UA_Client_run_iterate repeatedly until the connection is fully
* established. You can set a callback to client->config.stateCallback to be
* notified when the connection status changes. Or use UA_Client_getState to get
* the state manually. */

                     UA_ApplicationDescription **registeredServers);
/* Get a list of all known server in the network. Only supported by LDS servers.
* @param client to use. Must be connected to the same endpoint given in
* serverUrl or otherwise in disconnected state.
* @param serverUrl url to connect (for example "opc.tcp://localhost:4840")
* @param startingRecordId optional. Only return the records with an ID higher
          or equal the given. Can be used for pagination to only get a subset of
         the full list
* @param maxRecordsToReturn optional. Only return this number of records
* @param serverCapabilityFilterSize optional. Filter the returned list to only
          get servers with given capabilities, e.g. "LDS"
* @param serverCapabilityFilter optional. Filter the returned list to only get
        servers with given capabilities, e.g. "LDS"
* @param serverOnNetworkSize size of returned array, i.e., number of
        known/registered servers
 * @param serverOnNetwork array containing known/registered servers
```

8.6 Services

The raw OPC UA services are exposed to the client. But most of the time, it is better to use the convenience functions from ua_client_highlevel.h that wrap the raw services.

```
/* Don't use this function. Use the type versions below instead. */
void UA_THREADSAFE
__UA_Client_Service(UA_Client *client, const void *request,
                   const UA_DataType *requestType, void *response,
                   const UA_DataType *responseType);
/*
* Attribute Service Set
* ^^^^^^ */
UA_INLINABLE( UA_THREADSAFE UA_ReadResponse
UA_Client_Service_read(UA_Client *client, const UA_ReadRequest request) , (
    UA_ReadResponse response;
    __UA_Client_Service(client, &request, &UA_TYPES[UA_TYPES_READREQUEST],
                       &response, &UA_TYPES[UA_TYPES_READRESPONSE]);
    return response;
})
UA_INLINABLE( UA_THREADSAFE UA_WriteResponse
UA_Client_Service_write(UA_Client *client, const UA_WriteRequest request) , {
    UA_WriteResponse response;
    __UA_Client_Service(client, &request, &UA_TYPES[UA_TYPES_WRITEREQUEST],
                       &response, &UA_TYPES[UA_TYPES_WRITERESPONSE]);
   return response;
})
/*
* Historical Access Service Set
* ^^^^^^^ */
UA_INLINABLE( UA_THREADSAFE UA_HistoryReadResponse
UA_Client_Service_historyRead(UA_Client *client, const UA_HistoryReadRequest_
→request) ,{
    UA_HistoryReadResponse response;
    __UA_Client_Service(client, &request, &UA_TYPES[UA_TYPES_HISTORYREADREQUEST],
                                                                  (continues on next page)
```

```
&response, &UA_TYPES[UA_TYPES_HISTORYREADRESPONSE]);
    return response;
})
UA_INLINABLE( UA_THREADSAFE UA_HistoryUpdateResponse
UA_Client_Service_historyUpdate(UA_Client *client, const UA_HistoryUpdateRequest_

8.7 Asynchronous Services

All OPC UA services are asynchronous in nature. So several service calls can be made without waiting for the individual responses. Depending on the server's priorities responses may come in a different ordering than sent. Use the typed wrappers for async service requests instead of __UA_Client_AsyncService directly. See Async Services. However, the general mechanism of async service calls is explained here.

Connection and session management are performed in *UA_Client_run_iterate*, so to keep a connection healthy any client needs to consider how and when it is appropriate to do the call. This is especially true for the periodic renewal of a SecureChannel's SecurityToken which is designed to have a limited lifetime and will invalidate the connection if not renewed.

We say that an async service call has been dispatched once __UA_Client_AsyncService returns UA_STATUSCODE_GOOD. If there is an error after an async service has been dispatched, the callback is called with an "empty" response where the StatusCode has been set accordingly. This is also done if the client is shutting down and the list of dispatched async services is emptied.

The StatusCode received when the client is shutting down is UA_STATUSCODE_BADSHUTDOWN. The StatusCode received when the client doesn't receive response after the specified in config->timeout (can be overridden via the "timeoutHint" in the request header) is UA_STATUSCODE_BADTIMEOUT.

The userdata and requestId arguments can be NULL. The (optional) requestId output can be used to cancel the service while it is still pending. The requestId is unique for each service request. Alternatively the requestHandle can be manually set (non necessarily unique) in the request header for full service call. This can be used to cancel all outstanding requests using that handle together. Note that the client will auto-generate a requestHandle >100,000 if none is defined. Avoid these when manually setting a requetHandle in the requestHeader to avoid clashes.

```
typedef void (*UA_ClientAsyncServiceCallback)(UA_Client *client, void *userdata,
                                              UA_UInt32 requestId, void *response);
UA_StatusCode UA_THREADSAFE
__UA_Client_AsyncService(UA_Client *client, const void *request,
                         const UA_DataType *requestType,
                         UA_ClientAsyncServiceCallback callback,
                         const UA_DataType *responseType,
                         void *userdata, UA_UInt32 *requestId);
/* Cancel all dispatched requests with the given requestHandle.
* The number if cancelled requests is returned by the server.
* The output argument cancelCount is not set if NULL. */
UA_THREADSAFE UA_StatusCode
UA_Client_cancelByRequestHandle(UA_Client *client, UA_UInt32 requestHandle,
                                UA_UInt32 *cancelCount);
/* Map the requestId to the requestHandle used for that request and call the
* Cancel service for that requestHandle. */
UA_THREADSAFE UA_StatusCode
UA_Client_cancelByRequestId(UA_Client *client, UA_UInt32 requestId,
                            UA_UInt32 *cancelCount);
```

```
/* Set new userdata and callback for an existing request.
* @param client Pointer to the UA_Client
* @param requestId RequestId of the request, which was returned by
          __UA_Client_AsyncService before
* @param userdata The new userdata
* @param callback The new callback
* @return UA_StatusCode UA_STATUSCODE_GOOD on success
          UA_STATUSCODE_BADNOTFOUND when no request with requestId is found. */
UA_StatusCode UA_THREADSAFE
UA_Client_modifyAsyncCallback(UA_Client *client, UA_UInt32 requestId,
                              void *userdata, UA_ClientAsyncServiceCallback_
→callback);
/* Listen on the network and process arriving asynchronous responses in the
* background. Internal housekeeping, renewal of SecureChannels and subscription
* management is done as well. */

* SecureChannel during a downtime when no time-critical operations are
* performed. This method is asynchronous. The renewal is triggered (the OPN
* message is sent) but not completed. The OPN response is handled with
* ``UA_Client_run_iterate`` or a synchronous service-call operation.
* @return The return value is UA_STATUSCODE_GOODCALLAGAIN if the SecureChannel
           has not elapsed at least 75% of its lifetime. Otherwise the
           ``connectStatus`` is returned. */
UA_StatusCode UA_THREADSAFE
UA_Client_renewSecureChannel(UA_Client *client);
```

8.8 Timed Callbacks

Repeated callbacks can be attached to a client and will be executed in the defined interval.

```
typedef void (*UA_ClientCallback)(UA_Client *client, void *data);

/* Add a callback for execution at a specified time. If the indicated time lies
  * in the past, then the callback is executed at the next iteration of the
  * server's main loop.
  *
  * @param client The client object.
  * @param callback The callback that shall be added.
  * @param data Data that is forwarded to the callback.
  * @param date The timestamp for the execution time.
  * @param callbackId Set to the identifier of the repeated callback. This can
  * be used to cancel the callback later on. If the pointer is null, the
```

```
identifier is not set.
* @return Upon success, UA_STATUSCODE_GOOD is returned. An error code
           otherwise. */
UA_StatusCode UA_THREADSAFE
UA_Client_addTimedCallback(UA_Client *client, UA_ClientCallback callback,
                           void *data, UA_DateTime date, UA_UInt64 *callbackId);
/* Add a callback for cyclic repetition to the client.
* @param client The client object.
* @param callback The callback that shall be added.
* @param data Data that is forwarded to the callback.
* @param interval_ms The callback shall be repeatedly executed with the given
         interval (in ms). The interval must be positive. The first execution
          occurs at now() + interval at the latest.
* @param callbackId Set to the identifier of the repeated callback. This can
         be used to cancel the callback later on. If the pointer is null, the
          identifier is not set.
* @return Upon success, UA_STATUSCODE_GOOD is returned. An error code
           otherwise. */
UA_StatusCode UA_THREADSAFE
UA_Client_addRepeatedCallback(UA_Client *client, UA_ClientCallback callback,
                              void *data, UA_Double interval_ms,
                              UA_UInt64 *callbackId);
UA_StatusCode UA_THREADSAFE
UA_Client_changeRepeatedCallbackInterval(UA_Client *client,
                                         UA_UInt64 callbackId,
                                         UA_Double interval_ms);
void UA_THREADSAFE
UA_Client_removeCallback(UA_Client *client, UA_UInt64 callbackId);
#define UA_Client_removeRepeatedCallback(server, callbackId)
    UA_Client_removeCallback(server, callbackId);
```

8.9 Client Utility Functions

```
/* Lookup a datatype by its NodeId. Takes the custom types in the client
  * configuration into account. Return NULL if none found. */
const UA_DataType *
UA_Client_findDataType(UA_Client *client, const UA_NodeId *typeId);
```

8.9.1 Highlevel Client Functionality

The following definitions are convenience functions making use of the standard OPC UA services in the background. This is a less flexible way of handling the stack, because at many places sensible defaults are presumed; at the same time using these functions is the easiest way of implementing an OPC UA application, as you will not have to consider all the details that go into the OPC UA services. If more flexibility is needed, you can always achieve the same functionality using the raw OPC UA services.

Read Attributes

The following functions can be used to retrieve a single node attribute. Use the regular service to read several attributes at once.

```
/* Don't call this function, use the typed versions */
UA_StatusCode
__UA_Client_readAttribute(UA_Client *client, const UA_NodeId *nodeId,
                          UA_AttributeId attributeId, void *out,
                          const UA_DataType *outDataType);
UA_INLINABLE( UA_StatusCode
UA_Client_readNodeIdAttribute(UA_Client *client, const UA_NodeId nodeId,
                              UA_NodeId *outNodeId), {
    return __UA_Client_readAttribute(client, &nodeId, UA_ATTRIBUTEID_NODEID,
                                     outNodeId, &UA_TYPES[UA_TYPES_NODEID]);
})
UA_INLINABLE( UA_StatusCode
UA_Client_readNodeClassAttribute(UA_Client *client, const UA_NodeId nodeId,
                                 UA_NodeClass *outNodeClass), {
    return __UA_Client_readAttribute(client, &nodeId, UA_ATTRIBUTEID_NODECLASS,
                                     outNodeClass, &UA_TYPES[UA_TYPES_NODECLASS]);
})
UA_INLINABLE( UA_StatusCode
UA_Client_readBrowseNameAttribute(UA_Client *client, const UA_NodeId nodeId,

```

8.9.3 Asynchronous Operations

Many Services can be called with an array of operations. For example, a request to the Read Service contains an array of ReadValueId, each corresponding to a single read operation. For convenience, wrappers are provided to call single operations for the most common Services.

All async operations have a callback of the following structure: The returned StatusCode is split in two parts. The status indicates the overall success of the request and the operation. The result argument is non-NULL only if the status is no good.

```
typedef void
(*UA_ClientAsyncOperationCallback)(UA_Client *client, void *userdata,
                                   UA_UInt32 requestId, UA_StatusCode status,
                                   void *result);
```

8.9.4 Read Attribute

Asynchronously read a single attribute. The attribute is unpacked from the response as the datatype of the attribute is known ahead of time. Value attributes are variants.

Note that the last argument (value pointer) of the callbacks can be NULL if the status of the operation is not good.

```
/* Reading a single attribute */
typedef void
(*UA_ClientAsyncReadAttributeCallback)(UA_Client *client, void *userdata,
                                         UA_UInt32 requestId, UA_StatusCode status,
                                                                      (continues on next page)

8.9.8 Misc Functionalities

8.9.9 Subscriptions

Subscriptions in OPC UA are asynchronous. That is, the client sends several PublishRequests to the server. The server returns PublishResponses with notifications. But only when a notification has been generated. The client does not wait for the responses and continues normal operations.

Note the difference between Subscriptions and MonitoredItems. Subscriptions are used to report back notifications. MonitoredItems are used to generate notifications. Every MonitoredItem is attached to exactly one Subscription. And a Subscription can contain many MonitoredItems.

The client automatically processes PublishResponses (with a callback) in the background and keeps enough PublishRequests in transit. The PublishResponses may be recieved during a synchronous service call or in UA_Client_run_iterate. See more about asynchronicity.

```
/* Callbacks defined for Subscriptions */
typedef void (*UA_Client_DeleteSubscriptionCallback)
    (UA_Client *client, UA_UInt32 subId, void *subContext);
typedef void (*UA_Client_StatusChangeNotificationCallback)
    (UA_Client *client, UA_UInt32 subId, void *subContext,
    UA_StatusChangeNotification *notification);
/* Provides default values for a new subscription.
* RequestedPublishingInterval: 500.0 [ms]
* RequestedLifetimeCount: 10000
* RequestedMaxKeepAliveCount: 10
* MaxNotificationsPerPublish: 0 (unlimited)
* PublishingEnabled: true
* Priority: 0 */

        &response, &UA_TYPES[UA_TYPES_SETPUBLISHINGMODERESPONSE]);
    return response;
}
```

8.9.10 MonitoredItems

MonitoredItems for Events indicate the EventNotifier attribute. This indicates to the server not to monitor changes of the attribute, but to forward Event notifications from that node.

During the creation of a MonitoredItem, the server may return changed adjusted parameters. Check the returned UA_CreateMonitoredItemsResponse to get the current parameters.

```
/* Provides default values for a new monitored item. */
static UA_INLINE UA_MonitoredItemCreateRequest
UA_MonitoredItemCreateRequest_default(UA_NodeId nodeId) {
    UA_MonitoredItemCreateRequest request;
    UA_MonitoredItemCreateRequest_init(&request);
    request.itemToMonitor.nodeId = nodeId;
    request.itemToMonitor.attributeId = UA_ATTRIBUTEID_VALUE;
    request.monitoringMode = UA_MONITORINGMODE_REPORTING;
    request.requestedParameters.samplingInterval = 250;
    request.requestedParameters.discardOldest = true;
    request.requestedParameters.queueSize = 1;
    return request;
}
```

The clientHandle parameter cannot be set by the user, any value will be replaced by the client before sending the request to the server.

```
/* Callback for the deletion of a MonitoredItem */
typedef void (*UA_Client_DeleteMonitoredItemCallback)
    (UA_Client *client, UA_UInt32 subId, void *subContext,
    UA_UInt32 monId, void *monContext);

CHAPTER

NINE

PUBSUB

In PubSub the participating OPC UA Applications take their roles as Publishers and Subscribers. Publishers are the sources of data, while Subscribers consume that data. Communication in PubSub is message-based. Publishers send messages to a Message Oriented Middleware, without knowledge of what, if any, Subscribers there may be. Similarly, Subscribers express interest in specific types of data, and process messages that contain this data, without knowledge of what Publishers there are.

Message Oriented Middleware is software or hardware infrastructure that supports sending and receiving messages between distributed systems. OPC UA PubSub supports two different Message Oriented Middleware variants, namely the broker-less form and broker-based form. A broker-less form is where the Message Oriented Middleware is the network infrastructure that is able to route datagram-based messages. Subscribers and Publishers use datagram protocols like UDP. In a broker-based form, the core component of the Message Oriented Middleware is a message Broker. Subscribers and Publishers use standard messaging protocols like AMQP or MQTT to communicate with the Broker.

This makes PubSub suitable for applications where location independence and/or scalability are required.

The Publish/Subscribe (PubSub) extension for OPC UA enables fast and efficient 1:m communication. The PubSub extension is protocol agnostic and can be used with broker based protocols like MQTT and AMQP or brokerless implementations like UDP-Multicasting.

The configuration model for PubSub uses the following components:

```
typedef enum {
    UA_PUBSUB_COMPONENT_CONNECTION,
    UA_PUBSUB_COMPONENT_WRITERGROUP,
    UA_PUBSUB_COMPONENT_DATASETWRITER,
    UA_PUBSUB_COMPONENT_READERGROUP,
    UA_PUBSUB_COMPONENT_DATASETREADER
} UA_PUbSubComponentEnumType;
```

The open62541 PubSub API uses the following scheme:

- 1. Create a configuration for the needed PubSub element.
- 2. Call the add[element] function and pass in the configuration.
- 3. The add[element] function returns the unique nodeId of the internally created element.

Take a look on the PubSub Tutorials for more details about the API usage:

```
+-----+
| UA_Server |
```

```
+--> UA_PubSubConnection | UA_Server_addPubSubConnection
           +----+
       +---> UA_WriterGroup | UA_PubSubConnection_addWriterGroup
                +---> UA_DataSetWriter | UA_WriterGroup_addDataSetWriter_
   +----> UA_ReaderGroup | UA_PubSubConnection_addReaderGroup
  | f
                +---> UA_DataSetReader | UA_ReaderGroup_addDataSetReader_
                         +---> UA_SubscribedDataSet |
                                  +---> UA_TargetVariablesDataType |
                                  +-----+
```

9.1 PubSub Information Model Representation

The complete PubSub configuration is available inside the information model. The entry point is the node 'PublishSubscribe', located under the Server node. The standard defines for PubSub no new Service set. The configuration can optionally be done over methods inside the information model. The information model representation of the current PubSub configuration is generated automatically. This feature can be enabled/disabled by changing the UA_ENABLE_PUBSUB_INFORMATIONMODEL option.

9.2 Connections

The PubSub connections are the abstraction between the concrete transport protocol and the PubSub functionality. It is possible to create multiple connections with different transport protocols at runtime.

```
/* Valid PublisherId types from Part 14 */
typedef enum {
    UA_PUBLISHERIDTYPE_BYTE = 0,
    UA_PUBLISHERIDTYPE_UINT16 = 1,
    UA_PUBLISHERIDTYPE_UINT32 = 2,
    UA_PUBLISHERIDTYPE_UINT64 = 3,
    UA_PUBLISHERIDTYPE_STRING = 4
} UA_PublisherIdType;

/* Publisher Id
    Valid types are defined in Part 14, 7.2.2.2.2 NetworkMessage Layout:
```

```
Bit range 0-2: PublisherId Type
    000 The PublisherId is of DataType Byte This is the default value if_
→ExtendedFlags1 is omitted
    001 The PublisherId is of DataType UInt16
    010 The PublisherId is of DataType UInt32
    011 The PublisherId is of DataType UInt64
    100 The PublisherId is of DataType String
*/
typedef union {
    UA_Byte byte;
    UA_UInt16 uint16;
    UA_UInt32 uint32;
    UA_UInt64 uint64;
    UA_String string;
} UA_PublisherId;
typedef struct {
    UA_String name;
    UA_Boolean enabled;
    UA_PublisherIdType publisherIdType;
    UA_PublisherId publisherId;
    UA_String transportProfileUri;
    UA_Variant address;
    UA_KeyValueMap connectionProperties;
    UA_Variant connectionTransportSettings;
   UA_EventLoop *eventLoop; /* Use an external EventLoop (use the EventLoop of

    UA_StatusCode (*updateMonitoringInterval)(UA_Server *server, UA_NodeId Id,
                                              UA_PubSubComponentEnumType_
→eComponentType,
                                              UA_PubSubMonitoringType_
→eMonitoringType,
                                              void *data);
   UA_StatusCode (*deleteMonitoring)(UA_Server *server, UA_NodeId Id,
                                      UA_PubSubComponentEnumType eComponentType,
                                      UA_PubSubMonitoringType eMonitoringType, void_
→*data);
} UA_PubSubMonitoringInterface;
#endif /* UA_ENABLE_PUBSUB_MONITORING */
/* General PubSub configuration */
struct UA_PubSubConfiguration {
    /* Callback for PubSub component state changes: If provided this callback
    * informs the application about PubSub component state changes. E.g. state
    * change from operational to error in case of a DataSetReader
    * MessageReceiveTimeout. The status code provides additional
    * information. */
    void (*stateChangeCallback)(UA_Server *server, UA_NodeId *id,
                                UA_PubSubState state, UA_StatusCode status);
    UA_Boolean enableDeltaFrames;
#ifdef UA_ENABLE_PUBSUB_INFORMATIONMODEL
    UA_Boolean enableInformationModelMethods;
#endif
#ifdef UA_ENABLE_PUBSUB_ENCRYPTION
    /* PubSub security policies */
    size_t securityPoliciesSize;
    UA_PubSubSecurityPolicy *securityPolicies;
#endif
#ifdef UA_ENABLE_PUBSUB_MONITORING
   UA_PubSubMonitoringInterface monitoringInterface;
#endif
};
```

Add a new PubSub connection to the given server and open it. @param[in] server the server to add the connection to @param[in] connectionConfig the configuration for the newly added connection @param[out] connectionIdentifier if not NULL will be set to the identifier of the

@return UA_STATUSCODE_GOOD if connection was successfully added, otherwise an error code.

9.3 PublishedDataSets

The PublishedDataSets (PDS) are containers for the published information. The PDS contain the published variables and meta information. The metadata is commonly autogenerated or given as constant argument as part of the template functions. The template functions are standard defined and intended for configuration tools. You should normally create an empty PDS and call the functions to add new fields.

```
/* The UA_PUBSUB_DATASET_PUBLISHEDITEMS has currently no additional members and
* thus no dedicated config structure. */
typedef enum {
    UA_PUBSUB_DATASET_PUBLISHEDITEMS,
    UA_PUBSUB_DATASET_PUBLISHEDEVENTS,
    UA_PUBSUB_DATASET_PUBLISHEDITEMS_TEMPLATE,
    UA_PUBSUB_DATASET_PUBLISHEDEVENTS_TEMPLATE,
} UA_PublishedDataSetType;
typedef struct {
    UA_DataSetMetaDataType metaData;
    size_t variablesToAddSize;
    UA_PublishedVariableDataType *variablesToAdd;
} UA_PublishedDataItemsTemplateConfig;
typedef struct {
    UA_NodeId eventNotfier;
    UA_ContentFilter filter;
} UA_PublishedEventConfig;
```

```
typedef struct {
    UA_DataSetMetaDataType metaData;
    UA_NodeId eventNotfier;
    size_t selectedFieldsSize;
    UA_SimpleAttributeOperand *selectedFields;
    UA_ContentFilter filter;
} UA_PublishedEventTemplateConfig;
/* Configuration structure for PublishedDataSet */
typedef struct {
    UA_String name;
    UA_PublishedDataSetType publishedDataSetType;
        /* The UA_PUBSUB_DATASET_PUBLISHEDITEMS has currently no additional members
        * and thus no dedicated config structure.*/
       UA_PublishedDataItemsTemplateConfig itemsTemplate;
       UA_PublishedEventConfig event;
       UA_PublishedEventTemplateConfig eventTemplate;
    } config;
} UA_PublishedDataSetConfig;
UA_PublishedDataSetConfig_clear(UA_PublishedDataSetConfig *pdsConfig);
typedef struct {
   UA_StatusCode addResult;
    size_t fieldAddResultsSize;
    UA_StatusCode *fieldAddResults;
    UA_ConfigurationVersionDataType configurationVersion;
} UA_AddPublishedDataSetResult;
UA_AddPublishedDataSetResult UA_THREADSAFE
UA_Server_addPublishedDataSet(UA_Server *server,
                              const UA_PublishedDataSetConfig_
→*publishedDataSetConfig,
                              UA_NodeId *pdsId);
/* Returns a deep copy of the config */
UA_StatusCode UA_THREADSAFE
UA_Server_getPublishedDataSetConfig(UA_Server *server, const UA_NodeId pdsId,
                                    UA_PublishedDataSetConfig *config);
/* Returns a deep copy of the DataSetMetaData for an specific PDS */
UA_StatusCode UA_THREADSAFE
UA_Server_getPublishedDataSetMetaData(UA_Server *server, const UA_NodeId pdsId,
                                      UA_DataSetMetaDataType *metaData);
/* Remove PublishedDataSet, identified by the NodeId. Deletion of PDS removes
* all contained and linked PDS Fields. Connected WriterGroups will be also
```

```
* removed. */
UA_StatusCode UA_THREADSAFE
UA_Server_removePublishedDataSet(UA_Server *server, const UA_NodeId pdsId);
```

9.4 DataSetFields

The description of published variables is named DataSetField. Each DataSetField contains the selection of one information model node. The DataSetField has additional parameters for the publishing, sampling and error handling process.

```
typedef struct{
    UA_ConfigurationVersionDataType configurationVersion;
    UA_String fieldNameAlias;
    UA_Boolean promotedField;
    UA_PublishedVariableDataType publishParameters;
    /* non std. field */
    struct {
        UA_Boolean rtFieldSourceEnabled;
        /* If the rtInformationModelNode is set, the nodeid in publishParameter_
→must point
        * to a node with external data source backend defined
        * */
        UA_Boolean rtInformationModelNode;
        //TODO -> decide if suppress C++ warnings and use 'UA_DataValue * * const_
→staticValueSource; '
        UA_DataValue ** staticValueSource;
    } rtValueSource;
    UA_UInt32 maxStringLength;
} UA_DataSetVariableConfig;
typedef enum {
    UA_PUBSUB_DATASETFIELD_VARIABLE,
    UA_PUBSUB_DATASETFIELD_EVENT
} UA_DataSetFieldType;
typedef struct {
    UA_DataSetFieldType dataSetFieldType;
        /* events need other config later */
        UA_DataSetVariableConfig variable;
    } field;
} UA_DataSetFieldConfig;
void
UA_DataSetFieldConfig_clear(UA_DataSetFieldConfig *dataSetFieldConfig);
```

9.5 Custom Callback Implementation

The user can use his own callback implementation for publishing and subscribing. The user must take care of the callback to call for every publishing or subscibing interval

```
typedef struct {
    /* User's callback implementation. The user configured base time and timer_
→policy
    * will be provided as an argument to this callback so that the user can
    * implement his callback (thread) considering base time and timer policies */
    UA_StatusCode (*addCustomCallback)(UA_Server *server, UA_NodeId identifier,
                                       UA_ServerCallback callback,
                                       void *data, UA_Double interval_ms,
                                       UA_DateTime *baseTime, UA_TimerPolicy_
→timerPolicy,
                                       UA_UInt64 *callbackId);
   UA_StatusCode (*changeCustomCallback)(UA_Server *server, UA_NodeId identifier,
                                          UA_UInt64 callbackId, UA_Double interval_
⊶ms,
                                          UA_DateTime *baseTime, UA_TimerPolicy_
→timerPolicy);
    void (*removeCustomCallback)(UA_Server *server, UA_NodeId identifier, UA_UInt64_
⇔callbackId);
} UA_PubSub_CallbackLifecycle;
```

9.6 WriterGroup

All WriterGroups are created within a PubSubConnection and automatically deleted if the connection is removed. The WriterGroup is primary used as container for *DataSetWriter* and network message settings. The WriterGroup can be imagined as producer of the network messages. The creation of network messages is controlled by parameters like the publish interval, which is e.g. contained in the WriterGroup.

```
typedef enum {
    UA_PUBSUB_ENCODING_UADP = 0,
    UA_PUBSUB_ENCODING_JSON = 1,
    UA_PUBSUB_ENCODING_BINARY = 2
} UA_PubSubEncodingType;
```

9.7 WriterGroup

The message publishing can be configured for realtime requirements. The RT-levels go along with different requirements. The below listed levels can be configured:

UA_PUBSUB_RT_NONE - --> Description: Default "none-RT" Mode --> Requirements: - --> Restrictions: - UA_PUBSUB_RT_DIRECT_VALUE_ACCESS (Preview - not implemented) --> Description: Normally, the latest value for each DataSetField is read out of the information model. Within this RT-mode, the value source of each field configured as static pointer to an DataValue. The publish cycle won't use call the server read function. --> Requirements: All fields must be configured with a 'staticValueSource'. --> Restrictions: - UA_PUBSUB_RT_FIXED_LENGTH (Preview - not implemented) --> Description: All DataSetFields have a known, non-changing length. The server will pre-generate some buffers and use only memcopy operations to generate requested PubSub packages. --> Requirements: DataSetFields with variable size cannot be used within this mode. --> Restrictions: The configuration must be frozen and changes are not allowed while the WriterGroup is 'Operational'. UA_PUBSUB_RT_DETERMINISTIC (Preview - not implemented) --> Description: ---> Requirements: ---> Restrictions: --->

WARNING! For hard real time requirements the underlying system must be rt-capable.

```
typedef enum {
    UA_PUBSUB_RT_NONE = 0,
    UA_PUBSUB_RT_DIRECT_VALUE_ACCESS = 1,
    UA_PUBSUB_RT_FIXED_SIZE = 2,
    UA_PUBSUB_RT_DETERMINISTIC = 4,
} UA_PubSubRTLevel;

typedef struct {
    UA_String name;
    UA_Boolean enabled;
    UA_UInt16 writerGroupId;
    UA_Duration publishingInterval;
    UA_Double keepAliveTime;
    UA_Byte priority;
    UA_ExtensionObject transportSettings;
    UA_ExtensionObject messageSettings;
```

```
UA_KeyValueMap groupProperties;

                                       const UA_ByteString keyNonce);
#endif
```

9.8 DataSetWriter

The DataSetWriters are the glue between the WriterGroups and the PublishedDataSets. The DataSetWriter contain configuration parameters and flags which influence the creation of DataSet messages. These messages are encapsulated inside the network message. The DataSetWriter must be linked with an existing PublishedDataSet and be contained within a WriterGroup.

```
typedef struct {
    UA_String name;
    UA_UInt16 dataSetWriterId;
    UA_DataSetFieldContentMask dataSetFieldContentMask;
    UA_UInt32 keyFrameCount;
    UA_ExtensionObject messageSettings;
    UA_ExtensionObject transportSettings;
    UA_String dataSetName;
```

```
UA_KeyValueMap dataSetWriterProperties;
} UA_DataSetWriterConfig;
void
UA_DataSetWriterConfig_clear(UA_DataSetWriterConfig *pdsConfig);
/* Add a new DataSetWriter to an existing WriterGroup. The DataSetWriter must be
* coupled with a PublishedDataSet on creation.
* Part 14, 7.1.5.2.1 defines: The link between the PublishedDataSet and
* DataSetWriter shall be created when an instance of the DataSetWriterType is
* created. */
UA_StatusCode UA_THREADSAFE

9.9 SubscribedDataSet

SubscribedDataSet describes the processing of the received DataSet. SubscribedDataSet defines which field in the DataSet is mapped to which Variable in the OPC UA Application. SubscribedDataSet has two sub-types called the TargetVariablesType and SubscribedDataSetMirrorType. SubscribedDataSetMirrorType is currently not supported. SubscribedDataSet is set to TargetVariablesType and then the list of target Variables are created in the Subscriber AddressSpace. TargetVariables are a list of variables that are to be added in the Subscriber AddressSpace. It defines a list of Variable mappings between received DataSet fields and added Variables in the Subscriber AddressSpace.

```
UA_PUBSUB_SDS_TARGET,
    UA_PUBSUB_SDS_MIRROR
} UA_SubscribedDataSetEnumType;
typedef struct {
    /* Standard-defined FieldTargetDataType */
    UA_FieldTargetDataType targetVariable;
   /* If realtime-handling is required, set this pointer non-NULL and it will be_
⊶used
    * to memcpy the value instead of using the Write service.
    * If the beforeWrite method pointer is set, it will be called before a memcpy_
→update
     * to the value. But param externalDataValue already contains the new value.
     * If the afterWrite method pointer is set, it will be called after a memcpy_
⊶update
    * to the value. */
    UA_DataValue **externalDataValue;
    void *targetVariableContext; /* user-defined pointer */
    void (*beforeWrite)(UA_Server *server,
                        const UA_NodeId *readerIdentifier,
                        const UA_NodeId *readerGroupIdentifier,
                        const UA_NodeId *targetVariableIdentifier,
                        void *targetVariableContext,
                        UA_DataValue **externalDataValue);
    void (*afterWrite)(UA_Server *server,
                       const UA_NodeId *readerIdentifier,
                       const UA_NodeId *readerGroupIdentifier,
                       const UA_NodeId *targetVariableIdentifier,
                       void *targetVariableContext,
                       UA_DataValue **externalDataValue);
} UA_FieldTargetVariable;

9.10 DataSetReader

DataSetReader can receive NetworkMessages with the DataSetMessage of interest sent by the Publisher. DataSetReaders represent the configuration necessary to receive and process DataSetMessages on the Subscriber side. DataSetReader must be linked with a SubscribedDataSet and be contained within a ReaderGroup.

```
typedef enum {
    UA_PUBSUB_RT_UNKNOWN = 0,
    UA_PUBSUB_RT_VARIANT = 1,
    UA_PUBSUB_RT_DATA_VALUE = 2,
    UA_PUBSUB_RT_RAW = 4,
} UA_PubSubRtEncoding;
/* Parameters for PubSub DataSetReader Configuration */

```

9.11 ReaderGroup

ReaderGroup is used to group a list of DataSetReaders. All ReaderGroups are created within a Pub-SubConnection and automatically deleted if the connection is removed. All network message related filters are only available in the DataSetReader.

The RT-levels go along with different requirements. The below listed levels can be configured for a ReaderGroup.

- UA_PUBSUB_RT_NONE: RT applied to this level
- PUBSUB_CONFIG_FASTPATH_FIXED_OFFSETS: Extends PubSub RT functionality and implements fast path message decoding in the Subscriber. Uses a buffered network message and only decodes the necessary offsets stored in an offset buffer.

```
/* ReaderGroup configuration */
typedef struct {
    UA_String name;
    /* non std. field */
    UA_PubSubRTLevel rtLevel;
    UA_KeyValueMap groupProperties;
    UA_PubSubEncodingType encodingMimeType;
    UA_ExtensionObject transportSettings;
    /* Messages are decrypted if a SecurityPolicy is configured and the
    * securityMode set accordingly. The symmetric key is a runtime information
    * and has to be set via UA_Server_setReaderGroupEncryptionKey. */

                                       UA_ByteString signingKey,
                                       UA_ByteString encryptingKey,
                                       UA_ByteString keyNonce);
#endif
#ifdef UA_ENABLE_PUBSUB_SKS
```

9.12 SecurityGroup

A SecurityGroup is an abstraction that represents the message security settings and security keys for a subset of NetworkMessages exchanged between Publishers and Subscribers. The SecurityGroup objects are created on a Security Key Service (SKS). The SKS manages the access to the keys based on the role permission for a user assigned to a SecurityGroup Object. A SecurityGroup is identified with a unique identifier called the SecurityGroupId. It is unique within the SKS.

Note: The access to the SecurityGroup and therefore the securitykeys managed by SKS requires management of Roles and Permissions in the SKS. The Role Permission model is not supported at the time of writing. However, the access control plugin can be used to create and manage role permission on SecurityGroup object.

```
typedef struct {
    UA_String securityGroupName;
    UA_Duration keyLifeTime;
    UA_String securityPolicyUri;
    UA_UInt32 maxFutureKeyCount;
    UA_UInt32 maxPastKeyCount;
} UA_SecurityGroupConfig;
```

@brief Creates a SecurityGroup object and add it to the list in PubSub Manager. If the information model is enabled then the SecurityGroup object Node is also created in the server. A keyStorage with initial list of keys is created with a SecurityGroup. A callback is added to new SecurityGroup which updates the keys periodically at each KeyLifeTime expire.

@param server The server instance @param securityGroupFolderNodeId The parent node of the SecurityGroup. It must be of SecurityGroupFolderType @param securityGroupConfig The security settings of a SecurityGroup @param securityGroupNodeId The output nodeId of the new SecurityGroup @return UA StatusCode The return status code

@brief Removes the SecurityGroup from PubSub Manager. It removes the KeyStorage associated with the SecurityGroup from the server.

@param server The server instance @param securityGroup The nodeld of the securityGroup to be removed @return UA_StatusCode The returned status code.

```
UA_StatusCode UA_THREADSAFE
UA_Server_removeSecurityGroup(UA_Server *server, const UA_NodeId securityGroup);
```

@brief This is a repeated callback which is triggered on each iteration of SKS Pull request. The server uses this callback to notify user about the status of current Pull request iteration. The period is calculated based on the KeylifeTime of specified in the SecurityGroup object node on the SKS server.

@param server The server instance managing the publisher/subscriber. @param sksPullRequestStatus The current status of sks pull request. @param context The pointer to user defined data passed to this callback.

```
typedef void

(*UA_Server_sksPullRequestCallback)(UA_Server *server, UA_StatusCode_
→sksPullRequestStatus, void* context);
```

@brief Sets the SKS client config used to call the GetSecurityKeys Method on SKS and get the initial set of keys for a SecurityGroupId and adds timedCallback for the next GetSecurityKeys method Call. This uses async Client API for SKS Pull request. The SKS Client instance is created and destroyed at runtime on each iteration of SKS Pull request by the server. The key Rollover mechanism will check if the new keys are needed then it will call the getSecurityKeys Method on SKS Server. At the end of SKS Pull request iteration, the sks client will be deleted by a delayed callback (in next server iteration).

@note It is be called before setting Reader/Writer Group into Operational because this also allocates a channel context for the pubsub security policy.

@note the stateCallback of sksClientConfig will be overwritten by an internal callback.

@param server the server instance @param clientConfig holds the required configuration to make encrypted connection with SKS Server. The input client config takes the lifecycle as long as SKS request are made. It is deleted with its plugins when the server is deleted or the last Reader/Writer Group of the securityGroupId is deleted. The input config is copied to an internal config object and the content of input config object will be reset to zero. @param endpointUrl holds the endpointUrl of the SKS server @param securityGroupId the SecurityGroupId of the securityGroup on SKS and reader/writergroups @param callback the user defined callback to notify the user about the status of SKS Pull request. @param context passed to the callback function @return UA_StatusCode the retuned status

```
UA_StatusCode

UA_Server_setSksClient(UA_Server *server, UA_String securityGroupId,

UA_ClientConfig *clientConfig, const char *endpointUrl,

UA_Server_sksPullRequestCallback callback, void *context);

#define UA_WRITEMASK_VALUERANK
                                              (0x01u << 19u)
#define UA_WRITEMASK_WRITEMASK
                                              (0x01u << 20u)
```

```
#define UA_WRITEMASK_VALUEFORVARIABLETYPE (0x01u << 21u)
#define UA_WRITEMASK_ACCESSLEVELEX (0x01u << 25u)
```

10.4 ValueRank

The following are the most common ValueRanks used for Variables, VariableTypes and method arguments. ValueRanks higher than 3 are valid as well (but less common).

```
#define UA_VALUERANK_SCALAR_OR_ONE_DIMENSION -3
#define UA_VALUERANK_ANY -2
#define UA_VALUERANK_SCALAR -1
#define UA_VALUERANK_ONE_OR_MORE_DIMENSIONS 0
#define UA_VALUERANK_ONE_DIMENSION 1
#define UA_VALUERANK_TWO_DIMENSIONS 2
#define UA_VALUERANK_THREE_DIMENSIONS 3
```

10.5 EventNotifier

The following are the available EventNotifier used for Nodes. The EventNotifier Attribute is used to indicate if the Node can be used to subscribe to Events or to read / write historic Events. Part 3: 5.4 Table 10

```
#define UA_EVENTNOTIFIER_SUBSCRIBE_TO_EVENT (0x01u << 0u)
#define UA_EVENTNOTIFIER_HISTORY_READ (0x01u << 2u)
#define UA_EVENTNOTIFIER_HISTORY_WRITE (0x01u << 3u)
```

10.6 Rule Handling

The RuleHanding settings define how error cases that result from rules in the OPC UA specification shall be handled. The rule handling can be softened, e.g. to workaround misbehaving implementations or to mitigate the impact of additional rules that are introduced in later versions of the OPC UA specification.

```
typedef enum {
    UA_RULEHANDLING_DEFAULT = 0,
    UA_RULEHANDLING_ABORT, /* Abort the operation and return an error code */
    UA_RULEHANDLING_WARN, /* Print a message in the logs and continue */
    UA_RULEHANDLING_ACCEPT, /* Continue and disregard the broken rule */
} UA_RULEHANDLING;
```

10.7 Order

The Order enum is used to establish an absolute ordering between elements.

```
typedef enum {
   UA_ORDER_LESS = -1,
   UA_ORDER_EQ = 0,
   UA_ORDER_MORE = 1
} UA_Order;
```

10.8 Connection State

```
typedef enum {
    UA_CONNECTIONSTATE_CLOSED,
                                 /* The socket has been closed and the connection
                                   * will be deleted */
                                 /* The socket is open, but the HEL/ACK handshake
   UA_CONNECTIONSTATE_OPENING,
                                   * is not done */
   UA_CONNECTIONSTATE_ESTABLISHED,/* The socket is open and the connection
                                   * configured */
   UA_CONNECTIONSTATE_CLOSING /* The socket is closing down */
} UA_ConnectionState;
typedef enum {
    UA_SECURECHANNELSTATE_CLOSED = 0,
    UA_SECURECHANNELSTATE_REVERSE_LISTENING,
    UA_SECURECHANNELSTATE_CONNECTING,
    UA_SECURECHANNELSTATE_CONNECTED,
    UA_SECURECHANNELSTATE_REVERSE_CONNECTED,
    UA_SECURECHANNELSTATE_RHE_SENT,
    UA_SECURECHANNELSTATE_HEL_SENT,
    UA_SECURECHANNELSTATE_HEL_RECEIVED,
    UA_SECURECHANNELSTATE_ACK_SENT,
    UA_SECURECHANNELSTATE_ACK_RECEIVED,
   UA_SECURECHANNELSTATE_OPN_SENT,
    UA_SECURECHANNELSTATE_OPEN,
    UA_SECURECHANNELSTATE_CLOSING,
} UA_SecureChannelState;
typedef enum {
    UA_SESSIONSTATE_CLOSED = 0,
    UA_SESSIONSTATE_CREATE_REQUESTED,
    UA_SESSIONSTATE_CREATED,
    UA_SESSIONSTATE_ACTIVATE_REQUESTED,
    UA_SESSIONSTATE_ACTIVATED,
    UA_SESSIONSTATE_CLOSING
} UA_SessionState;
```

10.9 Statistic Counters

The stack manages statistic counters for SecureChannels and Sessions.

The Session layer counters are matching the counters of the ServerDiagnosticsSummaryDataType that are defined in the OPC UA Part 5 specification. The SecureChannel counters are not defined in the OPC UA spec, but are harmonized with the Session layer counters if possible.

```
typedef enum {
    UA_SHUTDOWNREASON_CLOSE = 0,
    UA_SHUTDOWNREASON_REJECT,
    UA_SHUTDOWNREASON_SECURITYREJECT,
    UA_SHUTDOWNREASON_TIMEOUT,
   UA_SHUTDOWNREASON_ABORT,
    UA_SHUTDOWNREASON_PURGE
} UA_ShutdownReason;
typedef struct {
    size_t currentChannelCount;
    size_t cumulatedChannelCount;
   size_t rejectedChannelCount;
    size_t channelTimeoutCount; /* only used by servers */
    size_t channelAbortCount;
    size_t channelPurgeCount; /* only used by servers */
} UA_SecureChannelStatistics;
typedef struct {
    size_t currentSessionCount;
    size_t cumulatedSessionCount;
    size_t securityRejectedSessionCount; /* only used by servers */
    size_t rejectedSessionCount;
    size_t sessionTimeoutCount;
                                       /* only used by servers */
                                       /* only used by servers */
    size_t sessionAbortCount;
} UA_SessionStatistics;
```

10.10 Lifecycle States

Generic lifecycle states. The STOPPING state indicates that the lifecycle is being terminated. But it might take time to (asynchronously) perform a graceful shutdown.

```
typedef enum {
    UA_LIFECYCLESTATE_STOPPED = 0,
    UA_LIFECYCLESTATE_STARTED,
    UA_LIFECYCLESTATE_STOPPING
} UA_LifecycleState;
```

10.11 Forward Declarations

Opaque pointers used in Client, Server and PubSub.

```
struct UA_Server;
typedef struct UA_Server UA_Server;
struct UA_ServerConfig;
typedef struct UA_ServerConfig UA_ServerConfig;

typedef void (*UA_ServerCallback)(UA_Server *server, void *data);
struct UA_Client;
typedef struct UA_Client UA_Client;
```

10.12 Range Definition

```
typedef struct {
    UA_UInt32 min;
    UA_UInt32 max;
} UA_UInt32Range;

typedef struct {
    UA_Duration min;
    UA_Duration max;
} UA_DurationRange;
```

10.13 Random Number Generator

If UA_MULTITHREADING is defined, then the seed is stored in thread local storage. The seed is initialized for every thread in the server/client.

```
void
UA_random_seed(UA_UInt64 seed);

UA_UInt32
UA_UInt32_random(void); /* no cryptographic entropy */

UA_Guid
UA_Guid_random(void); /* no cryptographic entropy */
```

10.14 Key Value Map

Helper functions to work with configuration parameters in an array of UA_KeyValuePair. Lookup is linear. So this is for small numbers of keys. The methods below that accept a *const UA_KeyValueMap* as an argument also accept NULL for that argument and treat it as an empty map.

```
typedef struct {
    size_t mapSize;
    UA_KeyValuePair *map;
} UA_KeyValueMap;
extern const UA_KeyValueMap UA_KEYVALUEMAP_NULL;
UA_KeyValueMap *
UA_KeyValueMap_new(void);
void
UA_KeyValueMap_clear(UA_KeyValueMap *map);
void
UA_KeyValueMap_delete(UA_KeyValueMap *map);
/* Is the map empty (or NULL)? */
UA Boolean
UA_KeyValueMap_isEmpty(const UA_KeyValueMap *map);
/* Does the map contain an entry for the key? */
UA Boolean
UA_KeyValueMap_contains(const UA_KeyValueMap *map, const UA_QualifiedName key);
/* Insert a copy of the value. Can reallocate the underlying array. This
* invalidates pointers into the previous array. If the key exists already, the
* value is overwritten (upsert semantics). */
UA_StatusCode
UA_KeyValueMap_set(UA_KeyValueMap *map,
                   const UA_QualifiedName key,
                   const UA_Variant *value);
/* Helper function for scalar insertion that internally calls
* `UA_KeyValueMap_set` */
UA StatusCode
UA_KeyValueMap_setScalar(UA_KeyValueMap *map,
                         const UA_QualifiedName key,
                         void *p,
                         const UA_DataType *type);
/* Returns a pointer to the value or NULL if the key is not found */
const UA_Variant *
UA_KeyValueMap_get(const UA_KeyValueMap *map,
                   const UA_QualifiedName key);
```

```
/* Returns NULL if the value for the key is not defined, not of the right
* datatype or not a scalar */
const void *
UA_KeyValueMap_getScalar(const UA_KeyValueMap *map,
                         const UA_QualifiedName key,
                         const UA_DataType *type);
/* Remove a single entry. To delete the entire map, use `UA_KeyValueMap_clear`. */
UA_StatusCode
UA_KeyValueMap_remove(UA_KeyValueMap *map,
                      const UA_QualifiedName key);
/* Create a deep copy of the given KeyValueMap */
UA_StatusCode
UA_KeyValueMap_copy(const UA_KeyValueMap *src, UA_KeyValueMap *dst);
/* Copy entries from the right-hand-side into the left-hand-size. Reallocates
* previous memory in the left-hand-side. If the operation fails, both maps are
* left untouched. */
UA_StatusCode
UA_KeyValueMap_merge(UA_KeyValueMap *lhs, const UA_KeyValueMap *rhs);
```

10.15 Binary Connection Config Parameters

```
typedef struct {
    UA_UInt32 protocolVersion;
    UA_UInt32 recvBufferSize;
    UA_UInt32 sendBufferSize;
    UA_UInt32 localMaxMessageSize; /* (0 = unbounded) */
    UA_UInt32 remoteMaxMessageSize; /* (0 = unbounded) */
    UA_UInt32 localMaxChunkCount; /* (0 = unbounded) */
    UA_UInt32 remoteMaxChunkCount; /* (0 = unbounded) */
    UA_UInt32 remoteMaxChunkCount; /* (0 = unbounded) */
} UA_ConnectionConfig;
```

10.16 Default Node Attributes

Default node attributes to simplify the use of the AddNodes services. For example, Setting the ValueRank and AccessLevel to zero is often an unintended setting and leads to errors that are hard to track down.

```
/* The default for variables is "BaseDataType" for the datatype, -2 for the
  * valuerank and a read-accesslevel. */
extern const UA_VariableAttributes UA_VariableAttributes_default;
extern const UA_VariableTypeAttributes UA_VariableTypeAttributes_default;
```

```
/* Methods are executable by default */
extern const UA_MethodAttributes UA_MethodAttributes_default;
/* The remaining attribute definitions are currently all zeroed out */
extern const UA_ObjectAttributes UA_ObjectAttributes_default;
extern const UA_ObjectTypeAttributes UA_ObjectTypeAttributes_default;
extern const UA_ReferenceTypeAttributes UA_ReferenceTypeAttributes_default;
extern const UA_DataTypeAttributes UA_DataTypeAttributes_default;
extern const UA_ViewAttributes UA_ViewAttributes_default;
```

10.17 Endpoint URL Parser

The endpoint URL parser is generally useful for the implementation of network layer plugins.

```
/* Split the given endpoint url into hostname, port and path. All arguments must
* be non-NULL. EndpointUrls have the form "opc.tcp://hostname:port/path", port
* and path may be omitted (together with the prefix colon and slash).
* @param endpointUrl The endpoint URL.
* @param outHostname Set to the parsed hostname. The string points into the
          original endpointUrl, so no memory is allocated. If an IPv6 address is
          given, hostname contains e.g. '[2001:0db8:85a3::8a2e:0370:7334]'
* @param outPort Set to the port of the url or left unchanged.
* @param outPath Set to the path if one is present in the endpointUrl. Can be
         NULL. Then not path is returned. Starting or trailing '/' are NOT
         included in the path. The string points into the original endpointUrl,
          so no memory is allocated.
* @return Returns UA_STATUSCODE_BADTCPENDPOINTURLINVALID if parsing failed. */
UA_StatusCode
UA_parseEndpointUrl(const UA_String *endpointUrl, UA_String *outHostname,
                    UA_UInt16 *outPort, UA_String *outPath);
/* Split the given endpoint url into hostname, vid and pcp. All arguments must
* be non-NULL. EndpointUrls have the form "opc.eth://<host>[:<VID>[.PCP]]".
* The host is a MAC address, an IP address or a registered name like a
* hostname. The format of a MAC address is six groups of hexadecimal digits,
* separated by hyphens (e.g. 01-23-45-67-89-ab). A system may also accept
* hostnames and/or IP addresses if it provides means to resolve it to a MAC
* address (e.g. DNS and Reverse-ARP).
* Note: currently only parsing MAC address is supported.
* @param endpointUrl The endpoint URL.
* @param vid Set to VLAN ID.
* @param pcp Set to Priority Code Point.
* @return Returns UA_STATUSCODE_BADINTERNALERROR if parsing failed. */
UA_StatusCode
UA_parseEndpointUrlEthernet(const UA_String *endpointUrl, UA_String *target,
```

```
UA_UInt16 *vid, UA_Byte *pcp);
/* Convert given byte string to a positive number. Returns the number of valid
* digits. Stops if a non-digit char is found and returns the number of digits
* up to that point. */
size_t
UA_readNumber(const UA_Byte *buf, size_t buflen, UA_UInt32 *number);
/* Same as UA_ReadNumber but with a base parameter */
size t
UA_readNumberWithBase(const UA_Byte *buf, size_t buflen,
                      UA_UInt32 *number, UA_Byte base);
#ifndef UA_MIN
#define UA_MIN(A, B) ((A) > (B) ? (B) : (A))
#endif
#ifndef UA MAX
#define UA_MAX(A, B) ((A) > (B) ? (A) : (B))
#endif
```

10.18 And-Escaping of Strings

The "and-escaping" of strings for is described in Part 4, A2. The & character is used to escape the reserved characters /.<>:#!&. So the string My. String becomes My&. String.

In addition to the standard we define "extended-and-escaping" where additionaly commas, semi-colons, brackets and whitespace characters are escaped. This improves the parsing in a larger context, as a lexer can find the end of the escaped string. The additionally reserved characters for the extended escaping are , ()[] \t\n\v\f\r.

This documentation always states whether "and-escaping" or the "extended-and-escaping is used.

10.19 Print and Parse RelativePath Expressions

Parse a RelativePath according to the format defined in Part 4, A2. This is used e.g. for the BrowsePath structure.

```
RelativePath := ( ReferenceType BrowseName )+
```

The ReferenceType has one of the following formats:

- /: HierarchicalReferences and subtypes
- .: Aggregates ReferenceTypes and subtypes
- < [!#]* BrowseName >: The ReferenceType is indicated by its BrowseName. Reserved characters in the BrowseName are and-escaped. The following prefix-modifiers are defined for the ReferenceType. -! switches to inverse References # excludes subtypes of the ReferenceType.
 - As a non-standard extension we allow the ReferenceType in angle-brackets

as a Nodeld. For example <ns=1; i=345>. If a string Nodeld is used, the string identifier is and-escaped.

The BrowseName is a QualifiedName. It consist of an optional NamespaceIndex and the name itself. The NamespaceIndex can be left out for the default Namespace zero. The name component is and-escaped (see above).

```
BrowseName := ([0-9] + ":")? Name
```

The last BrowseName in a RelativePath can be omitted. This acts as a wildcard that matches any BrowseName.

10.19.1 Example RelativePaths

```
• /2:Block&.Output
```

• /3:Truck.0:NodeVersion

• <0:HasProperty>1:Boiler/1:HeatSensor

• <0:HasChild>2:Wheel

<#Aggregates>1:Boiler/

• <!HasChild>Truck

• <HasChild>

10.20 Print and Parse SimpleAttributeOperand Expression

The SimpleAttributeOperand is used to specify the location of up values. SimpleAttributeOperands are used for example in EventFilters to select the values reported for each event instance.

The TypeDefinitionId is a NodeId and restricts the starting point for the lookup to instances of the TypeDefinitionNode or one of its subtypes. The NodeId defaults to the wildcard ns=0;i=0. The NodeId is extended-and-escaped.

The BrowsePath is a list of BrowseNames (QualifiedName expression with extended-and-escaping) to be followed from the TypeDefinitionNode instance. The implied ReferenceTypeIds (cf. the RelativePath expressions) are always the HierarchicalReferences and their subtypes. So the / separator is mandatory here. The BrowsePath for the SimpleAttributeOperand is defined to only follow into Variable- and ObjectNodes. If the BrowsePath is empty, the value is taken from the instance of the TypeDefinition itself.

The attribute is the textual name of the possible node attributes. For the index range, see the section on *NumericRange*.:

```
SimpleAttributeOperand :=
  TypeDefinitionId? SimpleBrowsePath ("#" Attribute)? ("[" IndexRange "]")?
SimpleBrowsePath := ("/" BrowseName)*
```

10.20.1 Example SimpleAttributeOperands

- ns=2;s=TruckEventType/3:Truck/5:Wheel#Value[1:3]
- /3:Truck/5:Wheel
- #BrowseName
- Empty String: No Nodeld, BrowsePath, Attribute and NumericRange. This indicates the value attribute of the event instance.

10.21 Convenience macros for complex types

```
#define UA_PRINTF_GUID_FORMAT "%08" PRIx32 "-%04" PRIx16 "-%04" PRIx16 \
    "-%02" PRIx8 "%02" PRIx8 "-%02" PRIx8 "%02" PRIx8 "%02"
```

10.22 Cryptography Helpers

```
/* Compare memory in constant time to mitigate timing attacks.
  * Returns true if ptr1 and ptr2 are equal for length bytes. */
UA_Boolean
UA_constantTimeEqual(const void *ptr1, const void *ptr2, size_t length);

/* Zero-out memory in a way that is not removed by compiler-optimizations. Use
  * this to ensure cryptographic secrets don't leave traces after the memory was
  * freed. */
void
UA_ByteString_memZero(UA_ByteString *bs);
```

CHAPTER

ELEVEN

XML NODESET COMPILER

When writing an application, it is more comfortable to create information models using some GUI tools. Most tools can export data according the OPC UA Nodeset XML schema. open62541 contains a Python based nodeset compiler that can transform these information model definitions into a working server.

Note that the nodeset compiler you can find in the *tools/nodeset_compiler* subfolder is *not* an XML transformation tool but a compiler. That means that it will create an internal representation when parsing the XML files and attempt to understand and verify the correctness of this representation in order to generate C Code.

11.1 Getting started

We take the following information model snippet as the starting point of the following tutorial. A more detailed tutorial on how to create your own information model and NodeSet2.xml can be found in this blog post: https://profanter.medium.com/how-to-create-custom-opc-ua-information-models-1e9a461f5b58

```
<UANodeSet xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
           xmlns:uax="http://opcfoundation.org/UA/2008/02/Types.xsd"
           xmlns="http://opcfoundation.org/UA/2011/03/UANodeSet.xsd"
           xmlns:s1="http://yourorganisation.org/example_nodeset/"

```

Take the previous snippet and save it to a file myNS.xml. To compile this nodeset into the corresponding C code, which can then be used by the open62541 stack, the nodeset compiler needs some arguments when you call it. The output of the help command gives you the following info:

```
$ python ./nodeset_compiler.py -h
usage: nodeset_compiler.py [-h] [-e <existingNodeSetXML>] [-x <nodeSetXML>]
                           [--internal-headers]
                           [-b <blacklistFile>] [-i <ignoreFile>]
                           [-t <typesArray>]
                           [-v]
                           <outputFile>
positional arguments:
 <outputFile>
                        The path/basename for the <output file>.c and <output
                        file>.h files to be generated. This will also be the
                        function name used in the header and c-file.
optional arguments:
 -h, --help
                        show this help message and exit
  -e <existingNodeSetXML>, --existing <existingNodeSetXML>
                        NodeSet XML files with nodes that are already present
                        on the server.
 -x <nodeSetXML>, --xml <nodeSetXML>
                        NodeSet XML files with nodes that shall be generated.
  --internal-headers
                        Include internal headers instead of amalgamated header
  -b <blacklistFile>, --blacklist <blacklistFile>
```

```
Loads a list of NodeIDs stored in blacklistFile (one
                      NodeID per line). Any of the nodeIds encountered in
                      this file will be removed from the nodeset prior to
                      compilation. Any references to these nodes will also
                      be removed
-i <ignoreFile>, --ignore <ignoreFile>
                      Loads a list of NodeIDs stored in ignoreFile (one
                      NodeID per line). Any of the nodeIds encountered in
                      this file will be kept in the nodestore but not
                      printed in the generated code
-t <typesArray>, --types-array <typesArray>
                      Types array for the given namespace. Can be used
                      mutliple times to define (in the same order as the
                      .xml files, first for --existing, then --xml) the type
                      arrays
--max-string-length MAX_STRING_LENGTH
                      Maximum allowed length of a string literal. If longer,
                      it will be set to an empty string
                      Make the script more verbose. Can be applied up to 4
-v, --verbose
                      times
```

So the resulting call looks like this:

```
$ python ./nodeset_compiler.py --types-array=UA_TYPES --existing ../../deps/ua-
→nodeset/Schema/Opc.Ua.NodeSet2.xml --xml myNS.xml myNS
```

And the output of the command:

The first argument <code>--types-array=UA_TYPES</code> defines the name of the global array in open62541 which contains the corresponding types used within the nodeset in <code>NodeSet2.xml</code>. If you do not define your own datatypes, you can always use the <code>UA_TYPES</code> value. More on that later in this tutorial. The next argument <code>--existing ../../deps/ua-nodeset/Schema/Opc.Ua.NodeSet2.xml</code> points to the XML definition of the standard-defined namespace <code>0</code> (NSO). Namespace <code>0</code> is assumed to be loaded beforehand and provides definitions for data type, reference types, and so. Since we reference nodes from NSO in our myNS.xml we need to tell the nodeset compiler that it should also load that nodeset, but not compile it into the output. Note that you may need to initialize the git submodule to get the deps/ua-nodeset folder (git submodule update <code>--init</code>) or download the full <code>NodeSet2.xml</code> manually. The argument <code>--xml</code> <code>myNS.xml</code> points to the user-defined information model, whose nodes will be added to the abstract syntax tree. The script will then create the files <code>myNS.c</code> and <code>myNS.h</code> (indicated by the last argument <code>myNS</code>) containing the C code necessary to instantiate those namespaces.

Although it is possible to run the compiler this way, it is highly discouraged. If you care to examine the CMakeLists.txt (examples/nodeset/CMakeLists.txt), you will find out that the file server_nodeset.xml is compiled using the following function:

```
ua_generate_nodeset(
    NAME "example"
    FILE "${PROJECT_SOURCE_DIR}/examples/nodeset/server_nodeset.xml"
    DEPENDS_TYPES "UA_TYPES"
    DEPENDS_NS "${UA_FILE_NS0}"
)
```

If you look into the files generated by the nodeset compiler, you will see that it generated a method called extern UA_StatusCode myNS(UA_Server *server);. You need to include the header and source file and then call the myNS(server) method right after creating the server instance with UA_Server_new. This will automatically add all the nodes to the server and return UA_STATUSCODE_GOOD if there weren't any errors. Additionally you need to compile the open62541 stack with the full NSO by setting UA_NAMESPACE_ZERO=FULL in CMake. Otherwise the stack uses a subset where many nodes are not included and thus adding a custom nodeset may fail.

This is how you can use the nodeset compiler to compile simple NodeSet XMLs to be used by the open62541 stack.

For your convenience and for simpler use we also provide a CMake function which simplifies the use of the ua_generate_datatypes and ua_generate_nodeset function even more. It is highly recommended to use this function: ua_generate_nodeset_and_datatypes. It uses some best practice settings and you only need to pass a name and the nodeset files. Passing the .csv and .bsd files is optional and if not given, generating datatypes for that noteset will be skipped. You can also define dependencies between nodesets using the DEPENDS argument.

Here are some examples for the DI and PLCOpen nodesets:

```
# Generate types and namespace for DI
ua_generate_nodeset_and_datatypes(
    NAME "di"
    FILE_CSV "${UA_NODESET_DIR}/DI/Opc.Ua.Di.NodeIds.csv"
    FILE_BSD "${UA_NODESET_DIR}/DI/Opc.Ua.Di.Types.bsd"
    FILE_NS "${UA_NODESET_DIR}/DI/Opc.Ua.Di.NodeSet2.xml"
)

# generate PLCopen namespace which is using DI
ua_generate_nodeset_and_datatypes(
    NAME "plc"
    # PLCopen does not define custom types. Only generate the nodeset
    FILE_NS "${UA_NODESET_DIR}/PLCopen/Opc.Ua.PLCopen.NodeSet2_V1.02.xml"
    # PLCopen depends on the di nodeset, which must be generated before
    DEPENDS "di"
)
```

11.2 Creating object instances

One of the key benefits of defining object types is being able to create object instances fairly easily. Object instantiation is handled automatically when the typedefinition Nodeld points to a valid ObjectType node. All Attributes and Methods contained in the objectType definition will be instantiated along with the object node.

While variables are copied from the objectType definition (allowing the user for example to attach new dataSources to them), methods are always only linked. This paradigm is identical to languages like C++: The method called is always the same piece of code, but the first argument is a pointer to an object. Likewise, in OPC UA, only one methodCallback can be attached to a specific methodNode. If that methodNode is called, the parent objectId will be passed to the method - it is the methods job to derefence which object instance it belongs to in that moment.

Let's look at an example that will create a pump instance given the newly defined objectType from myNS.xml:

```
/* This work is licensed under a Creative Commons CCZero 1.0 Universal License.
* See http://creativecommons.org/publicdomain/zero/1.0/ for more information. */
#include <signal.h>
#include <stdio.h>
#include "open62541.h"
/* Files myNS.h and myNS.c are created from myNS.xml */
#include "myNS.h"
UA_Boolean running = true;
static void stopHandler(int sign) {
    UA_LOG_INFO(UA_Log_Stdout, UA_LOGCATEGORY_SERVER, "received ctrl-c");
    running = false;
}
int main(int argc, char **argv) {
    signal(SIGINT, stopHandler);
    signal(SIGTERM, stopHandler);
    UA_Server *server = UA_Server_new();
    UA_ServerConfig_setDefault(UA_Server_getConfig(server));
    UA_StatusCode retval = myNS(server);
    /* Create nodes from nodeset */
    if(retval != UA_STATUSCODE_GOOD) {
       UA_LOG_ERROR(UA_Log_Stdout, UA_LOGCATEGORY_SERVER, "Could not add the_
→example nodeset. "
            "Check previous output for any error.");
        retval = UA_STATUSCODE_BADUNEXPECTEDERROR;
    } else {
       UA_NodeId createdNodeId;
       UA_ObjectAttributes object_attr = UA_ObjectAttributes_default;
```

```
object_attr.description = UA_LOCALIZEDTEXT("en-US", "A pump!");
        object_attr.displayName = UA_LOCALIZEDTEXT("en-US", "Pump1");
        // we assume that the myNS nodeset was added in namespace 2.
        // You should always use UA_Server_addNamespace to check what the
       // namespace index is for a given namespace URI. UA_Server_addNamespace
        // will just return the index if it is already added.
       UA_Server_addObjectNode(server, UA_NODEID_NUMERIC(1, 0),
                                UA_NODEID_NUMERIC(0, UA_NS0ID_OBJECTSFOLDER),
                                UA_NODEID_NUMERIC(0, UA_NS0ID_ORGANIZES),
                                UA_QUALIFIEDNAME(1, "Pump1"),
                                UA_NODEID_NUMERIC(2, 1002),
                                object_attr, NULL, &createdNodeId);
        retval = UA_Server_run(server, &running);
    }
    UA_Server_delete(server);
    return (int) retval;
}
```

Make sure you have updated the headers and libs in your project, then recompile and run the server. Make especially sure you have added myNS. h to your include folder.

As you can see instantiating an object is not much different from creating an object node. The main difference is that you *must* use an objectType node as typeDefinition.

If you start the server and inspect the nodes with UA Expert, you will find the pump in the objects folder, which look like this Fig. 11.1.

Fig. 11.1: Instantiated Pump Object with inherited children

As you can see the pump has inherited its parents attributes (ManufacturerName and ModelName).

Methods, in contrast to objects and variables, are never cloned but instead only linked. The reason is that you will quite propably attach a method callback to a central method, not each object. Objects are instantiated if they are below the object you are creating, so any object (like an object called associatedServer of ServerType) that is part of pump will be instantiated as well. Objects above you object are never instantiated, so the same ServerType object in Fielddevices would have been omitted (the reason is that the recursive instantiation function protects itself from infinite recursions, which are hard to track when first ascending, then redescending into a tree).

11.3 Combination of multiple nodesets

In the previous section you have seen how you can use the nodeset compiler with one single nodeset which depends on the default nodeset (NSO) Opc. Ua. NodeSet2. xml. The nodeset compiler also supports nodesets which depend on more than one nodeset. We will show this use-case with the PLCopen nodeset. The PLCopen nodeset Opc.Ua.PLCopen.NodeSet2_V1.02.xml depends on the DI nodeset Opc.Ua.Di.NodeSet2.xml which then depends on NSO. This example is also shown in examples/nodeset/CMakeLists.txt.

This DI nodeset makes use of some additional data types in deps/ua-nodeset/DI/Opc.Ua.Di.Types. bsd. Since we also need these types within the generated code, we first need to compile the types into C code. The generated code is mainly a definition of the binary representation of the types required for encoding and decoding. The generation can be done using the ua_generate_datatypes CMake function, which uses the tools/generate_datatypes.py script:

```
ua_generate_datatypes(
    NAME "ua_types_di"
    TARGET_SUFFIX "types-di"
    FILE_CSV "${UA_NODESET_DIR}/DI/Opc.Ua.Di.NodeIds.csv"
    FILES_BSD "${UA_NODESET_DIR}/DI/Opc.Ua.Di.Types.bsd"
)
```

The NAMESPACE_MAP parameter is an array of strings which indicates the mapping of specific namespace uris to the resulting namespace index. This mapping is required for correct mapping of DataType nodes and their node ids. Currently we need to rely that the namespace is also added at this position in the final server. There is no automatic inferring yet (pull requests are warmly welcome). If you are using the DEPENDS option on the ua_generate_nodeset_and_datatypes, the NAMESPACE_MAP is also inherited and you do not need to pass all mappings for dependent types. The CSV and BSD files contain the metadata and definition for the types. TARGET_SUFFIX is used to create a new target with the name open62541-generator-TARGET_SUFFIX.

The ``NAMESPACE_MAP`` parameter is deprecated and no longer has any effect. The index of the nodeset is set automatically when it is loaded.

Now you can compile the DI nodeset XML using the following command:

```
ua_generate_nodeset(
    NAME "di"
    FILE "${UA_NODESET_DIR}/DI/Opc.Ua.Di.NodeSet2.xml"
    TYPES_ARRAY "UA_TYPES_DI"
    INTERNAL
    DEPENDS_TYPES "UA_TYPES"
                  "${UA_NODESET_DIR}/Schema/Opc.Ua.NodeSet2.xml"
    DEPENDS_NS
```

```
DEPENDS_TARGET "open62541-generator-types-di"
```

There are now two new arguments: INTERNAL indicates that internal headers (and non public API) should be included within the generated source code. This is currently required for nodesets which use structures as data values, and will probably be fixed in the future. The DEPENDS_TYPES types array argument is matched with the nodesets in the same order as they appear on the DEPENDS_TARGET parameter. It tells the nodeset compiler which types array it should use: UA_TYPES for Opc.Ua. NodeSet2.xml and UA_TYPES_DI for Opc.Ua.Di.NodeSet2.xml. This is the type array generated by the generate_datatypes.py script. The rest is similar to the example in previous section: Opc.Ua. NodeSet2.xml is assumed to exist already and only needs to be loaded for consistency checks, Opc. Ua.Di.NodeSet2.xml will be generated in the output file ua_namespace_di.c/.h

Next we can generate the PLCopen nodeset. Since it doesn't require any additional datatype definitions, we can immediately start with the nodeset compiler command:

```
ua_generate_nodeset(
    NAME "plc"
    FILE "${UA_NODESET_DIR}/PLCopen/Opc.Ua.PLCopen.NodeSet2_V1.02.xml"
    INTERNAL
    DEPENDS_TYPES
        "UA_TYPES" "UA_TYPES_DI"
    DEPENDS_NS
        "${UA_NODESET_DIR}/Schema/Opc.Ua.NodeSet2.xml"
        "${UA_NODESET_DIR}/DI/Opc.Ua.Di.NodeSet2.xml"
        DEPENDS_TARGET "open62541-generator-ns-di"
)
```

This call is quite similar to the compilation of the DI nodeset. As you can see, we do not define any specific types array for the PLCopen nodeset. Since the PLCopen nodeset depends on the NSO and DI nodeset, we need to tell the nodeset compiler that these two nodesets should be seen as already existing. Make sure that the order is the same as in your XML file, e.g., in this case the order indicated in Opc.Ua.PLCopen.NodeSet2_V1.02.xml -> UANodeSet -> Models -> Model.

As a result of the previous scripts you will have multiple source files:

- ua_types_di_generated.c
- ua_types_di_generated.h
- ua_types_di_generated_encoding_binary.h
- ua_types_di_generated_handling.h
- ua namespace di.c
- ua namespace di.h
- ua_namespace_plc.c
- ua_namespace_plc.h

Finally you need to include all these files in your build process and call the corresponding initialization methods for the nodesets. An example application could look like this:

```
UA_Server *server = UA_Server_new();
UA_ServerConfig_setDefault(UA_Server_getConfig(server));
/* Create nodes from nodeset */
UA_StatusCode retval = ua_namespace_di(server);
if(retval != UA_STATUSCODE_GOOD) {
    UA_LOG_ERROR(UA_Log_Stdout, UA_LOGCATEGORY_SERVER,
                 "Adding the DI namespace failed. Please check previous error_
→output.");
    UA_Server_delete(server);
    return (int)UA_STATUSCODE_BADUNEXPECTEDERROR;
}
retval |= ua_namespace_plc(server);
if(retval != UA_STATUSCODE_GOOD) {
    UA_LOG_ERROR(UA_Log_Stdout, UA_LOGCATEGORY_SERVER,
                 "Adding the PLCopen namespace failed. Please check previous error_
→output.");
    UA_Server_delete(server);
    return (int)UA_STATUSCODE_BADUNEXPECTEDERROR;
}
retval = UA_Server_run(server, &running);
```

11.4 Outstanding Companion Spec Issues

There are some Companion Specifications that currently cannot be compiled with the Nodeset compiler. Which Companion Specifications are affected and what causes this is described below.

· Safety, Glass, DEXPI

Do not specify a BSD file or BSD blob in the XML file. The BSD file is considered deprecated. However, it is currently still required by the Nodeser compiler.

• I4AAS, RSL, FDI

Attempting to load will result in a runtime error ("Type-checking failed with error code BadTypeMismatch" or "Parent node not found").

• BACnet

Defines data types whose fields have the names signed or unsigned. This leads to errors when creating C structures, because signed and unsigned are keywords in C.

11.5 Automatic Nodesetinjection

The nodesetinjector is a mechanism for automatically loading nodeset/companion specifications during server initialization. It provides a fast and easy way to load nodesets in all applications, focusing on the official OPCFoundation/UANodeset Repository (https://github.com/OPCFoundation/UA-Nodeset). Specify the required information models using CMake.

Which nodesets are to be loaded is determined by the Cmake flag DUA_INFORMATION_MODEL_AUTOLOAD. All nodesets that are to be loaded automatically are listed here. The naming is based on the folder name of the Companion Specification in the ua-nodeset folder.

A CMake call could look like this.

- -DCMAKE_BUILD_TYPE=Debug
- -DUA_BUILD_EXAMPLES=ON
- -DUA_INFORMATION_MODEL_AUTOLOAD=DI; POWERLINK; PROFINET; MachineVision
- -DUA_NAMESPACE_ZERO=FULL

The order of nodesets is important! Nodesets that build on other nodesets must be placed after them in the list. The following nodesets are currently supported.

 DI, CNC, ISA95-JOBCONTROL, OpenSCS, AMB, AutoID, POWERLINK, IA, Machinery, PackML, PNEM, PLCopen, MachineTool, PROFINET, MachineVision, FDT, CommercialKitchenEquipment, PNRIO, Scales, Weihenstephan, Pumps, CAS, TMC, IJT

CHAPTER

TWELVE

PLUGIN API

12.1 Logging Plugin API

Servers and clients define a logger in their configuration. The logger is a plugin. A default plugin that logs to stdout is provided as an example. The logger plugin is stateful and can point to custom data. So it is possible to keep open file handlers in the logger context.

Every log message consists of a log level, a log category and a string message content. The timestamp of the log message is created within the logger.

```
typedef enum {
    UA_LOGLEVEL_TRACE = 100,
    UA_LOGLEVEL_DEBUG

12.2 Node Store Plugin API

Warning!! The structures defined in this section are only relevant for the developers of custom Nodestores. The interaction with the information model is possible only via the OPC UA *Services*. So the following sections are purely informational so that users may have a clear mental model of the underlying representation.

12.2.1 Node Lifecycle: Constructors, Destructors and Node Contexts

To finalize the instantiation of a node, a (user-defined) constructor callback is executed. There can be both a global constructor for all nodes and node-type constructor specific to the TypeDefinition of the new node (attached to an ObjectTypeNode or VariableTypeNode).

In the hierarchy of ObjectTypes and VariableTypes, only the constructor of the (lowest) type defined for the new node is executed. Note that every Object and Variable can have only one isTypeOf reference. But type-nodes can technically have several hasSubType references to implement multiple inheritance. Issues of (multiple) inheritance in the constructor need to be solved by the user.

When a node is destroyed, the node-type destructor is called before the global destructor. So the overall node lifecycle is as follows:

- 1. Global Constructor (set in the server config)
- 2. Node-Type Constructor (for VariableType or ObjectTypes)
- 3. (Usage-period of the Node)
- 4. Node-Type Destructor
- 5. Global Destructor

The constructor and destructor callbacks can be set to NULL and are not used in that case. If the node-type constructor fails, the global destructor will be called before removing the node. The destructors are assumed to never fail.

Every node carries a user-context and a constructor-context pointer. The user-context is used to attach custom data to a node. But the (user-defined) constructors and destructors may replace the user-context pointer if they wish to do so. The initial value for the constructor-context is NULL. When the AddNodes service is used over the network, the user-context pointer of the new node is also initially set to NULL.

Global Node Lifecycle

Global constructor and destructor callbacks used for every node type. To be set in the server config.

```
typedef struct {
   /* Can be NULL. May replace the nodeContext */
   UA_StatusCode (*constructor)(UA_Server *server,
                                 const UA_NodeId *sessionId, void *sessionContext,
                                 const UA_NodeId *nodeId, void **nodeContext);
   /* Can be NULL. The context cannot be replaced since the node is destroyed
    * immediately afterwards anyway. */
   void (*destructor)(UA_Server *server,
                       const UA_NodeId *sessionId, void *sessionContext,
                       const UA_NodeId *nodeId, void *nodeContext);
   /* Can be NULL. Called during recursive node instantiation. While mandatory
    * child nodes are automatically created if not already present, optional child
    * nodes are not. This callback can be used to define whether an optional child
    * node should be created.
    * @param server The server executing the callback
    * @param sessionId The identifier of the session
    * @param sessionContext Additional data attached to the session in the
            access control laver
    * @param sourceNodeId Source node from the type definition. If the new node
            shall be created, it will be a copy of this node.
    * @param targetParentNodeId Parent of the potential new child node
    * @param referenceTypeId Identifies the reference type which that the parent
             node has to the new node.
    * @return Return UA_TRUE if the child node shall be instantiated,
              UA_FALSE otherwise. */
   UA_Boolean (*createOptionalChild)(UA_Server *server,
                                      const UA_NodeId *sessionId,
                                      void *sessionContext,
                                      const UA_NodeId *sourceNodeId,
                                      const UA_NodeId *targetParentNodeId,
                                      const UA_NodeId *referenceTypeId);
   /* Can be NULL. Called when a node is to be copied during recursive
    * node instantiation. Allows definition of the NodeId for the new node.
    * If the callback is set to NULL or the resulting NodeId is UA_NODEID_
\rightarrowNUMERIC(X,0)
    * an unused nodeid in namespace X will be used. E.g. passing UA_NODEID_NULL_
∽will
    * result in a NodeId in namespace 0.
    * @param server The server executing the callback
    * @param sessionId The identifier of the session
    * @param sessionContext Additional data attached to the session in the
         access control layer
```

Node Type Lifecycle

Constructor and destructors for specific object and variable types.

12.2.2 ReferenceType Bitfield Representation

ReferenceTypes have an alternative represention as an index into a bitfield for fast comparison. The index is generated when the corresponding ReferenceTypeNode is added. By bounding the number of ReferenceTypes that can exist in the server, the bitfield can represent a set of an combination of ReferenceTypes.

Every ReferenceTypeNode contains a bitfield with the set of all its subtypes. This speeds up the Browse services substantially.

The following ReferenceTypes have a fixed index. The NSO bootstrapping creates these Reference-Types in-order.

```
#define UA_REFERENCETYPEINDEX_REFERENCES 0
#define UA_REFERENCETYPEINDEX_HASSUBTYPE 1
#define UA_REFERENCETYPEINDEX_AGGREGATES 2
#define UA_REFERENCETYPEINDEX_HIERARCHICALREFERENCES 3
```

```
#define UA REFERENCETYPEINDEX NONHIERARCHICALREFERENCES 4
#define UA_REFERENCETYPEINDEX_HASCHILD 5
#define UA_REFERENCETYPEINDEX_ORGANIZES 6
#define UA_REFERENCETYPEINDEX_HASEVENTSOURCE 7
#define UA_REFERENCETYPEINDEX_HASMODELLINGRULE 8
#define UA_REFERENCETYPEINDEX_HASENCODING 9
#define UA_REFERENCETYPEINDEX_HASDESCRIPTION 10
#define UA_REFERENCETYPEINDEX_HASTYPEDEFINITION 11
#define UA_REFERENCETYPEINDEX_GENERATESEVENT 12
#define UA_REFERENCETYPEINDEX_HASPROPERTY 13
#define UA_REFERENCETYPEINDEX_HASCOMPONENT 14
#define UA_REFERENCETYPEINDEX_HASNOTIFIER 15
#define UA_REFERENCETYPEINDEX_HASORDEREDCOMPONENT 16
#define UA_REFERENCETYPEINDEX_HASINTERFACE 17
/* The maximum number of ReferrenceTypes. Must be a multiple of 32. */
#define UA_REFERENCETYPESET_MAX 128
typedef struct {
    UA_UInt32 bits[UA_REFERENCETYPESET_MAX / 32];
} UA_ReferenceTypeSet;
extern const UA_ReferenceTypeSet UA_REFERENCETYPESET_NONE;
extern const UA_ReferenceTypeSet UA_REFERENCETYPESET_ALL;
static UA_INLINE void
UA_ReferenceTypeSet_init(UA_ReferenceTypeSet *set) {
    memset(set, 0, sizeof(UA_ReferenceTypeSet));
}
static UA_INLINE UA_ReferenceTypeSet

    UA_Byte i = index / 32, j = index % 32;
    UA_ReferenceTypeSet set;
    UA_ReferenceTypeSet_init(&set);
    set.bits[i] |= ((UA_UInt32)1) << j;</pre>
    return set;
}
static UA_INLINE UA_ReferenceTypeSet
UA_ReferenceTypeSet_union(const UA_ReferenceTypeSet setA,
                          const UA_ReferenceTypeSet setB) {
    UA_ReferenceTypeSet set;
    for(size_t i = 0; i < UA_REFERENCETYPESET_MAX / 32; i++)</pre>
        set.bits[i] = setA.bits[i] | setB.bits[i];
    return set;
}
static UA_INLINE UA_Boolean
UA_ReferenceTypeSet_contains(const UA_ReferenceTypeSet *set, UA_Byte index) {
```

```
UA_Byte i = index / 32, j = index % 32;
return !!(set->bits[i] & (((UA_UInt32)1) << j));
}</pre>
```

12.2.3 Node Pointer

The "native" format for reference between nodes is the ExpandedNodeld. That is, references can also point to external servers. In practice, most references point to local nodes using numerical Nodelds from the standard-defined namespace zero. In order to save space (and time), pointer-tagging is used for compressed "NodePointer" representations. Numerical Nodelds are immediately contained in the pointer. Full Nodelds and ExpandedNodelds are behind a pointer indirection. If the Nodestore supports it, a NodePointer can also be an actual pointer to the target node.

Depending on the processor architecture, some numerical Nodelds don't fit into an immediate encoding and are kept as pointers. ExpandedNodelds may be internally translated to "normal" Nodelds. Use the provided functions to generate NodePointers that fit the assumptions for the local architecture.

```
/* Forward declaration. All node structures begin with the NodeHead. */
struct UA_NodeHead;
typedef struct UA_NodeHead UA_NodeHead;
/* Tagged Pointer structure. */
typedef union {
    uintptr_t immediate;
                                        /* 00: Small numerical NodeId */
                                        /* 01: Pointer to NodeId */
    const UA_NodeId *id;
    const UA_ExpandedNodeId *expandedId; /* 10: Pointer to ExternalNodeId */
    const UA_NodeHead *node;
                                        /* 11: Pointer to a node */
} UA_NodePointer;
/* Sets the pointer to an immediate NodeId "ns=0;i=0" similar to a freshly
* initialized UA_NodeId */
static UA_INLINE void
UA_NodePointer_init(UA_NodePointer *np) { np->immediate = 0; }
/* NodeId and ExpandedNodeId targets are freed */
void
UA_NodePointer_clear(UA_NodePointer *np);
/* Makes a deep copy */
UA_StatusCode
UA_NodePointer_copy(UA_NodePointer in, UA_NodePointer *out);
/* Test if an ExpandedNodeId or a local NodeId */
UA Boolean
UA_NodePointer_isLocal(UA_NodePointer np);
UA_Order
UA_NodePointer_order(UA_NodePointer p1, UA_NodePointer p2);
```

```
static UA_INLINE UA_Boolean
UA_NodePointer_equal(UA_NodePointer p1, UA_NodePointer p2) {
    return (UA_NodePointer_order(p1, p2) == UA_ORDER_EQ);
}
/* Cannot fail. The resulting NodePointer can point to the memory from the
* NodeId. Make a deep copy if required. */
UA_NodePointer
UA_NodePointer_fromNodeId(const UA_NodeId *id);
/* Cannot fail. The resulting NodePointer can point to the memory from the
* ExpandedNodeId. Make a deep copy if required. */
UA NodePointer
UA_NodePointer_fromExpandedNodeId(const UA_ExpandedNodeId *id);
/* Can point to the memory from the NodePointer */
UA_ExpandedNodeId
UA_NodePointer_toExpandedNodeId(UA_NodePointer np);
/* Can point to the memory from the NodePointer. Discards the ServerIndex and
* NamespaceUri of a potential ExpandedNodeId inside the NodePointer. Test
* before if the NodePointer is local. */
UA NodeId
UA_NodePointer_toNodeId(UA_NodePointer np);
```

12.2.4 Base Node Attributes

Nodes contain attributes according to their node type. The base node attributes are common to all node types. In the OPC UA *Services*, attributes are referred to via the *NodeId* of the containing node and an integer *Attribute Id*.

Internally, open62541 uses UA_Node in places where the exact node type is not known or not important. The nodeClass attribute is used to ensure the correctness of casting from UA_Node to a specific node type.

```
struct {
        struct UA_ReferenceTargetTreeElem *left;
        struct UA_ReferenceTargetTreeElem *right;
    } nameTreeEntry;
} UA_ReferenceTargetTreeElem;
/* List of reference targets with the same reference type and direction. Uses
* either an array or a tree structure. The SDK will not change the type of
* reference target structure internally. The nodestore implementations may
* switch internally when a node is updated.
* The recommendation is to switch to a tree once the number of refs > 8. */
typedef struct {
    union {
        /* Organize the references in an array. Uses less memory, but incurs
         * lookups in linear time. Recommended if the number of references is
         * known to be small. */
       UA_ReferenceTarget *array;
       /* Organize the references in a tree for fast lookup. Use
        * UA_Node_addReference and UA_Node_deleteReference to modify the
        * tree-structure. The binary tree implementation (and absolute ordering
        * / duplicate browseNames are allowed) are not exposed otherwise in the
         * public API. */
        struct {
            UA_ReferenceTargetTreeElem *idRoot; /* Lookup based on target id */
            UA_ReferenceTargetTreeElem *nameRoot; /* Lookup based on browseName*/
        } tree;
    } targets;
    size_t targetsSize;
    UA_Boolean hasRefTree; /* RefTree or RefArray? */
    UA_Byte referenceTypeIndex;
    UA_Boolean isInverse;
} UA_NodeReferenceKind;
/* Iterate over the references. Aborts when the first callback return a non-NULL
* pointer and returns that pointer. Do not modify the reference targets during
* the iteration. */
typedef void *
(*UA_NodeReferenceKind_iterateCallback)(void *context, UA_ReferenceTarget *target);
void *
UA_NodeReferenceKind_iterate(UA_NodeReferenceKind *rk,
                             UA_NodeReferenceKind_iterateCallback callback,
                             void *context);
/* Returns the entry for the targetId or NULL if not found */
const UA_ReferenceTarget *
```

```
UA_NodeReferenceKind_findTarget(const UA_NodeReferenceKind *rk,
                                const UA_ExpandedNodeId *targetId);
/* Switch between array and tree representation. Does nothing upon error (e.g.
* out-of-memory). */
UA_StatusCode
UA_NodeReferenceKind_switch(UA_NodeReferenceKind *rk);
/* Singly-linked LocalizedText list */
typedef struct UA_LocalizedTextListEntry {
    struct UA_LocalizedTextListEntry *next;
    UA_LocalizedText localizedText;
} UA_LocalizedTextListEntry;
/* Every Node starts with these attributes */
struct UA_NodeHead {
    UA_NodeId nodeId;
    UA_NodeClass nodeClass:
    UA_QualifiedName browseName;
    /* A node can have different localizations for displayName and description.
    * The server selects a suitable localization depending on the locale ids
    * that are set for the current session.
    * Locales are added simply by writing a LocalizedText value with a new
    * locale. A locale can be removed by writing a LocalizedText value of the
    * corresponding locale with an empty text field. */
    UA_LocalizedTextListEntry *displayName;
    UA_LocalizedTextListEntry *description;
    UA_UInt32 writeMask;
    size_t referencesSize;
    UA_NodeReferenceKind *references;

    UA_MonitoredItem *monitoredItems; /* MonitoredItems for Events and immediate
                                       * DataChanges (no sampling interval). */
#endif
};
```

12.2.5 VariableNode

```
/* Indicates whether a variable contains data inline or whether it points to an
* external data source */
typedef enum {
   UA_VALUESOURCE_DATA,
    UA_VALUESOURCE_DATASOURCE
} UA_ValueSource;
typedef struct {
    /* Called before the value attribute is read. It is possible to write into the
    * value attribute during onRead (using the write service). The node is
    * re-opened afterwards so that changes are considered in the following read
    * operation.
    * @param handle Points to user-provided data for the callback.
    * @param nodeid The identifier of the node.
    * @param data Points to the current node value.
    * @param range Points to the numeric range the client wants to read from
              (or NULL). */
    void (*onRead)(UA_Server *server, const UA_NodeId *sessionId,
                   void *sessionContext, const UA_NodeId *nodeid,
                   void *nodeContext, const UA_NumericRange *range,
                   const UA_DataValue *value);
    /* Called after writing the value attribute. The node is re-opened after
    * writing so that the new value is visible in the callback.
    * @param server The server executing the callback
     * @sessionId The identifier of the session
    * @sessionContext Additional data attached to the session
                      in the access control layer
    * @param nodeid The identifier of the node.
     * @param nodeUserContext Additional data attached to the node by
             the user.
    * @param nodeConstructorContext Additional data attached to the node
            by the type constructor(s).
    * @param range Points to the numeric range the client wants to write to (or
             NULL). */
    void (*onWrite)(UA_Server *server, const UA_NodeId *sessionId,
                    void *sessionContext, const UA_NodeId *nodeId,
                    void *nodeContext, const UA_NumericRange *range,
                    const UA_DataValue *data);
} UA_ValueCallback;
typedef struct {
    /* Copies the data from the source into the provided value.
    * !! ZERO-COPY OPERATIONS POSSIBLE !!
     * It is not required to return a copy of the actual content data. You can
                                                                    (continues on next page)
```

```
* return a pointer to memory owned by the user. Memory can be reused
 * between read callbacks of a DataSource, as the result is already encoded
 * on the network buffer between each read operation.
* To use zero-copy reads, set the value of the `value->value` Variant
* without copying, e.g. with `UA_Variant_setScalar`. Then, also set
* `value->value.storageType` to `UA_VARIANT_DATA_NODELETE` to prevent the
* memory being cleaned up. Don't forget to also set `value->hasValue` to
* true to indicate the presence of a value.
* @param server The server executing the callback
* @param sessionId The identifier of the session
* @param sessionContext Additional data attached to the session in the
         access control layer
* @param nodeId The identifier of the node being read from
* @param nodeContext Additional data attached to the node by the user
* @param includeSourceTimeStamp If true, then the datasource is expected to
        set the source timestamp in the returned value
 * @param range If not null, then the datasource shall return only a
         selection of the (nonscalar) data. Set
         UA_STATUSCODE_BADINDEXRANGEINVALID in the value if this does not
         apply
* @param value The (non-null) DataValue that is returned to the client. The
        data source sets the read data, the result status and optionally a
         sourcetimestamp.
* @return Returns a status code for logging. Error codes intended for the
          original caller are set in the value. If an error is returned,
          then no releasing of the value is done
*/
UA_StatusCode (*read)(UA_Server *server, const UA_NodeId *sessionId,
                     void *sessionContext, const UA_NodeId *nodeId,
                     void *nodeContext, UA_Boolean includeSourceTimeStamp,
                     const UA_NumericRange *range, UA_DataValue *value);
/* Write into a data source. This method pointer can be NULL if the
* operation is unsupported.
* @param server The server executing the callback
* @param sessionId The identifier of the session
* @param sessionContext Additional data attached to the session in the
        access control layer
* @param nodeId The identifier of the node being written to
 * @param nodeContext Additional data attached to the node by the user
 * @param range If not NULL, then the datasource shall return only a
         selection of the (nonscalar) data. Set
         UA_STATUSCODE_BADINDEXRANGEINVALID in the value if this does not
         apply
* @param value The (non-NULL) DataValue that has been written by the client.
         The data source contains the written data, the result status and
```

Value Callback

Value Callbacks can be attached to variable and variable type nodes. If not NULL, they are called before reading and after writing respectively.

```
typedef struct {
    /* Called before the value attribute is read. The external value source can be
    * be updated and/or locked during this notification call. After this function_
→returns
    * to the core, the external value source is readed immediately.
    UA_StatusCode (*notificationRead)(UA_Server *server, const UA_NodeId *sessionId,
                                      void *sessionContext, const UA_NodeId *nodeid,

    UA_ViewNode viewNode;
} UA_Node;
```

12.2.14 Nodestore

The following definitions are used for implementing custom node storage backends. **Most users will** want to use the default nodestore and don't need to work with the nodestore API.

Outside of custom nodestore implementations, users should not manually edit nodes. Please use the OPC UA services for that. Otherwise, all consistency checks are omitted. This can crash the application eventually.

```
typedef void (*UA_NodestoreVisitor)(void *visitorCtx, const UA_Node *node);

typedef struct {
    /* Nodestore context and lifecycle */
    void *context;
    void (*clear)(void *nsCtx);
```

```
/* The following definitions are used to create empty nodes of the different
* node types. The memory is managed by the nodestore. Therefore, the node
* has to be removed via a special deleteNode function. (If the new node is
* not added to the nodestore.) */
UA_Node * (*newNode)(void *nsCtx, UA_NodeClass nodeClass);
void (*deleteNode)(void *nsCtx, UA_Node *node);
/* ``Get`` returns a pointer to an immutable node. Call ``releaseNode`` to
* indicate when the pointer is no longer accessed.
* It can be indicated if only a subset of the attributes and referencs need
 * to be accessed. That is relevant when the nodestore accesses a slow
 * storage backend for the attributes. The attribute mask is a bitfield with
 * ORed entries from UA_NodeAttributesMask.
 * The returned node always contains the context-pointer and other fields
* specific to open626541 (not official attributes).
* The NodeStore does not complain if attributes and references that don't
* exist (for that node) are requested. Attributes and references in
* addition to those specified can be returned. For example, if the full
* node already is kept in memory by the Nodestore. */
const UA_Node * (*getNode)(void *nsCtx, const UA_NodeId *nodeId,
                           UA_UInt32 attributeMask,

12.3 Access Control Plugin API

The access control callback is used to authenticate sessions and grant access rights accordingly.

The sessionId and sessionContext can be both NULL. This is the case when, for example, a MonitoredItem (the underlying Subscription) is detached from its Session but continues to run.

```
struct UA_AccessControl {
   void *context;
   void (*clear)(UA_AccessControl *ac);
   /* Supported login mechanisms. The server endpoints are created from here. */
   size_t userTokenPoliciesSize;
   UA_UserTokenPolicy *userTokenPolicies;
   /* Authenticate a session. The session context is attached to the session
    * and later passed into the node-based access control callbacks. The new
    * session is rejected if a StatusCode other than UA_STATUSCODE_GOOD is
    * returned.
    * Note that this callback can be called several times for a Session. For
    * example when a Session is recovered (activated) on a new
    * SecureChannel. */
   UA_StatusCode (*activateSession)(UA_Server *server, UA_AccessControl *ac,
                                     const UA_EndpointDescription_
→*endpointDescription,
                                     const UA_ByteString_
→*secureChannelRemoteCertificate,
                                     const UA_NodeId *sessionId,
                                     const UA_ExtensionObject *userIdentityToken,
                                     void **sessionContext);
   /* Deauthenticate a session and cleanup */
```

```
void (*closeSession)(UA_Server *server, UA_AccessControl *ac,
                        const UA_NodeId *sessionId, void *sessionContext);
   /* Access control for all nodes*/
   UA_UInt32 (*getUserRightsMask)(UA_Server *server, UA_AccessControl *ac,
                                  const UA_NodeId *sessionId, void *sessionContext,
                                  const UA_NodeId *nodeId, void *nodeContext);
   /* Additional access control for variable nodes */

};
```

12.4 Event Loop Subsystem

An OPC UA-enabled application can have several clients and servers. And server can serve different transport-level protocols for OPC UA. The EventLoop is a central module that provides a unified control-flow for all of these. Hence, several applications can share an EventLoop.

The EventLoop and the ConnectionManager implementation is architecture-specific. The goal is to have a single call to "poll" (epoll, kqueue, ...) in the EventLoop that covers all ConnectionManagers. Hence the EventLoop plugin implementation must know implementation details of the Connection-Manager implementations. So the EventLoop can extract socket information, etc. from the ConnectionManagers.

12.4.1 Timer Policies

A timer comes with a cyclic interval in which a callback is executed. If an application is congested the interval can be missed. Two different policies can be used when this happens. Either schedule the next execution after the interval has elapsed again from the current time onwards or stay within the regular interval with respect to the original basetime.

```
typedef enum {
    UA_TIMER_HANDLE_CYCLEMISS_WITH_CURRENTTIME,
    UA_TIMER_HANDLE_CYCLEMISS_WITH_BASETIME
} UA_TimerPolicy;
```

12.4.2 Event Loop

The EventLoop implementation is part of the selected architecture. For example, "Win32/POSIX" stands for a Windows environment with an EventLoop that uses the POSIX API. Several EventLoops can be instantiated in parallel. But the globally defined functions are the same everywhere.

```
typedef void (*UA_Callback)(void *application, void *context);
/* Delayed callbacks are executed not when they are registered, but in the
* following EventLoop cycle */
typedef struct UA_DelayedCallback {
    struct UA_DelayedCallback *next; /* Singly-linked list */
    UA_Callback callback;
    void *application;
    void *context;
} UA_DelayedCallback;
typedef enum {
    UA_EVENTLOOPSTATE_FRESH = 0,
    UA_EVENTLOOPSTATE_STOPPED,
    UA_EVENTLOOPSTATE_STARTED,
    UA_EVENTLOOPSTATE_STOPPING /* Stopping in progress, needs EventLoop
                                * cycles to finish */
} UA_EventLoopState;
```

```
struct UA_EventLoop {
   /* Configuration
    * The configuration should be set before the EventLoop is started */
   const UA_Logger *logger;
    /* See the implementation-specific documentation for possible parameters.
    * The params map is cleaned up when the EventLoop is _free'd. */
   UA_KeyValueMap params;
    /* EventLoop Lifecycle
    * The EventLoop state also controls the state of the configured
    * EventSources. Stopping the EventLoop gracefully closes e.g. the open
    * network connections. The only way to process incoming events is to call
    * the 'run' method. Events are then triggering their respective callbacks
    * from within that method.*/
    const volatile UA_EventLoopState state; /* Only read the state from outside */
    /* Start the EventLoop and start all already registered EventSources */
   UA_StatusCode (*start)(UA_EventLoop *el);
    /* Stop all EventSources. This is asynchronous and might need a few
    * iterations of the main-loop to succeed. */
    void (*stop)(UA_EventLoop *el);
    /* Process events for at most "timeout" ms or until an unrecoverable error
    * occurs. If timeout==0, then only already received events are
    * processed. */
    UA_StatusCode (*run)(UA_EventLoop *el, UA_UInt32 timeout);
   /* Clean up the EventLoop and free allocated memory. Can fail if the
    * EventLoop is not stopped. */
    UA_StatusCode (*free)(UA_EventLoop *el);
    /* EventLoop Time Domain
    * Each EventLoop instance can manage its own time domain. This affects the
    * execution of timed callbacks and time-based sending of network packets.
    * Managing independent time domains is important when different parts of
     * the same system are synchronized to different external master clocks.
    * Each EventLoop uses a "normal" and a "monotonic" clock. The monotonic
    * clock does not (necessarily) conform to the current wallclock date. But
    * its time intervals are more precise. So it is used for all internally
    * scheduled events of the EventLoop (e.g. timed callbacks and time-based
     * sending of network packets). The normal and monotonic clock sources can
```

```
* be configured via parameters before starting the EventLoop. See the
 * architecture-specific documentation for that.
 * Note that the logger configured in the EventLoop generates timestamps
 * independently. If the logger uses a different time domain than the
 * EventLoop, discrepancies may appear in the logs.
 * The EventLoop clocks can be read via the following functions. See
 * `open62541/types.h` for the documentation of their equivalent globally
 * defined functions. */
UA_DateTime (*dateTime_now)(UA_EventLoop *el);
UA_DateTime (*dateTime_nowMonotonic)(UA_EventLoop *el);
UA_Int64
           (*dateTime_localTimeUtcOffset)(UA_EventLoop *el);
/* Timed Callbacks
* Cyclic callbacks are executed regularly with an interval.
* A timed callback is executed only once. */
/* Time of the next cyclic callback. Returns the max DateTime if no cyclic
* callback is registered. */
UA_DateTime (*nextCyclicTime)(UA_EventLoop *el);
/* The execution interval is in ms. Returns the callbackId if the pointer is
* non-NULL. */
UA_StatusCode
(*addCyclicCallback)(UA_EventLoop *el, UA_Callback cb, void *application,
                     void *data, UA_Double interval_ms, UA_DateTime *baseTime,
                     UA_TimerPolicy timerPolicy, UA_UInt64 *callbackId);
UA_StatusCode

```

12.4.3 Event Source

Event Sources are attached to an EventLoop. Typically the event source and the EventLoop are developed together and share a private API in the background.

```
} UA_EventSourceType;
struct UA_EventSource {
    struct UA_EventSource *next; /* Singly-linked list for use by the
                                 * application that registered the ES */
    UA_EventSourceType eventSourceType;
    /* Configuration
    * ~~~~~ */
                                  /* Unique name of the ES */
    UA_String name;
    UA_EventLoop *eventLoop;
                                  /* EventLoop where the ES is registered */
    UA_KeyValueMap params;
    /* Lifecycle
    * ~~~~~ */
   UA_EventSourceState state;
    UA_StatusCode (*start)(UA_EventSource *es);
    void (*stop)(UA_EventSource *es); /* Asynchronous. Iterate theven EventLoop
                                      * until the EventSource is stopped. */
   UA_StatusCode (*free)(UA_EventSource *es);
};
```

12.4.4 Connection Manager

Every Connection is created by a ConnectionManager. Every ConnectionManager belongs to just one application. A ConnectionManager can act purely as a passive "Factory" for Connections. But it can also be stateful. For example, it can keep a session to an MQTT broker open which is used by individual connections that are each bound to an MQTT topic.

```
* - The msg ByteString is the message (or packet) received on the
   connection. Can be empty. */
typedef void
(*UA_ConnectionManager_connectionCallback)
     (UA_ConnectionManager *cm, uintptr_t connectionId,
     void *application, void **connectionContext, UA_ConnectionState state,
     const UA_KeyValueMap *params, UA_ByteString msg);
struct UA_ConnectionManager {
    /* Every ConnectionManager is treated like an EventSource from the
    * perspective of the EventLoop. */
   UA_EventSource eventSource;
    /* Name of the protocol supported by the ConnectionManager. For example
    * "mqtt", "udp", "mqtt". */
    UA_String protocol;
    /* Open a Connection
     * Connecting is asynchronous. The connection-callback is called when the
     * connection is open (status=GOOD) or aborted (status!=GOOD) when
    * connecting failed.
    * Some ConnectionManagers can also passively listen for new connections.
     * Configuration parameters for this are passed via the key-value list. The
     * `context` pointer of the listening connection is also set as the initial
    * context of newly opened connections.
    * The parameters describe the connection. For example hostname and port
     * (for TCP). Other protocols (e.g. MQTT, AMQP, etc.) may required
     * additional arguments to open a connection in the key-value list.
     * The provided context is set as the initial context attached to this
     * connection. It is already set before the first call to
     * connectionCallback.
     * The connection can be opened synchronously or asynchronously.
     * - For synchronous connection, the connectionCallback is called with the
        status UA_CONNECTIONSTATE_ESTABLISHED immediately from within the
        openConnection operation.
     * - In the asynchronous case the connectionCallback is called immediately
        from within the openConnection operation with the status
       UA_CONNECTIONSTATE_OPENING. The connectionCallback is called with the
        status UA_CONNECTIONSTATE_ESTABLISHED once the connection has fully
        opened.
```

```
* Note that a single call to openConnection might open multiple
    * connections. For example listening on IPv4 and IPv6 for a single
    * hostname. Each protocol implementation documents whether multiple
    * connections might be opened at once. */
    UA_StatusCode
    (*openConnection)(UA_ConnectionManager *cm, const UA_KeyValueMap *params,
                     void *application, void *context,
                     UA_ConnectionManager_connectionCallback connectionCallback);
    /* Send a message over a Connection
     * Sending is asynchronous. That is, the function returns before the message
    * is ACKed from remote. The memory for the buffer is expected to be
     * allocated with allocNetworkBuffer and is released internally (also if
     * sending fails).
    * Some ConnectionManagers can accept additional parameters for sending. For
    * example a tx-time for sending in time-synchronized TSN settings. */
    UA_StatusCode
    (*sendWithConnection)(UA_ConnectionManager *cm, uintptr_t connectionId,
                         const UA_KeyValueMap *params, UA_ByteString *buf);
    /* Close a Connection
    * When a connection is closed its `connectionCallback` is called with
    * (status=BadConnectionClosed, msg=empty). Then the connection is cleared
    * up inside the ConnectionManager. This is the case both for connections
    * that are actively closed and those that are closed remotely. The return
    * code is non-good only if the connection is already closed. */
    (*closeConnection)(UA_ConnectionManager *cm, uintptr_t connectionId);
    /* Buffer Management
    * ~~~~~~~~~~
    * Each ConnectionManager allocates and frees his own memory for the network
    * buffers. This enables, for example, zero-copy neworking mechanisms. The
    * connectionId is part of the API to enable cases where memory is
    * statically allocated for every connection */
    UA_StatusCode
    (*allocNetworkBuffer)(UA_ConnectionManager *cm, uintptr_t connectionId,
                         UA_ByteString *buf, size_t bufSize);
    void
    (*freeNetworkBuffer)(UA_ConnectionManager *cm, uintptr_t connectionId,
                        UA_ByteString *buf);
};
```

12.4.5 Interrupt Manager

The Interrupt Manager allows to register to listen for system interrupts. Triggering the interrupt calls the callback associated with it.

The implementations of the interrupt manager for the different platforms shall be designed such that:

Registered interrupts are only intercepted from within the running EventLoop

Processing an interrupt in the EventLoop is handled similarly to handling a network event: all methods and also memory allocation are available from within the interrupt callback.

```
/* Interrupts can have additional key-value 'instanceInfos' for each individual
* triggering. See the architecture-specific documentation. */
typedef void
(*UA_InterruptCallback)(UA_InterruptManager *im,
                        uintptr_t interruptHandle, void *interruptContext,
                        const UA_KeyValueMap *instanceInfos);
struct UA_InterruptManager {
    /* Every InterruptManager is treated like an EventSource from the
    * perspective of the EventLoop. */
    UA_EventSource eventSource;
    /* Register an interrupt. The handle and context information is passed
    * through to the callback.
    * The interruptHandle is a numerical identifier of the interrupt. In some
    * cases, such as POSIX signals, this is enough information to register
    * callback. For other interrupt systems (architectures) additional
     * parameters may be required and can be passed in via the parameters
     * key-value list. See the implementation-specific documentation.
    * The interruptContext is opaque user-defined information and passed
    * through to the callback without modification. */
    UA_StatusCode
    (*registerInterrupt)(UA_InterruptManager *im, uintptr_t interruptHandle,
                         const UA_KeyValueMap *params,
                         UA_InterruptCallback callback, void *interruptContext);
    /* Remove a registered interrupt. Returns no error code if the interrupt is
     * already deregistered. */
    (*deregisterInterrupt)(UA_InterruptManager *im, uintptr_t interruptHandle);
};
#if defined(UA_ARCHITECTURE_POSIX) || defined(UA_ARCHITECTURE_WIN32)
```

12.4.6 POSIX EventLop Implementation

The POSIX compatibility of Win32 is 'close enough'. So a joint implementation is provided.

Configuration parameters (only Linux and BSDs, must be set before start to take effect): - 0:clock-source [int32]: Clock source (default: CLOCK_REALTIME). - 0:clock-source-monotonic [int32]: Clock source used for time intervals. A

non-monotonic source can be used as well. But expect accordingly longer sleep-times for timed events when the clock is set to the past. See the man-page of "clock_gettime" on how to get a clock source id for a character-device such as /dev/ptp0. (default: CLOCK MONOTONIC RAW)*/

TCP Connection Manager

Listens on the network and manages TCP connections. This should be available for all architectures.

The *openConnection* callback is used to create both client and server sockets. A server socket listens and accepts incoming connections (creates an active connection). This is distinguished by the key-value parameters passed to *openConnection*. Note that a single call to *openConnection* for a server connection may actually create multiple connections (one per hostname / device).

The *connectionCallback* of the server socket and *context* of the server socket is reused for each new connection. But the key-value parameters for the first callback are different between server and client connections.

Configuration parameters for the ConnectionManager (set before _start): - 0:recv-bufsize [uint32]: Size of the buffer that is statically allocated

for receiving messages (default: 65536).

• 0:send-bufsize [uint32]: Size of the statically allocated buffer for sending messages. This then becomes an upper bound for the message size. If undefined a fresh buffer is allocated for every *allocNetworkBuffer* (default: no buffer).

Open Connection Parameters: - 0:address [string | array of string]: Hostname or IPv4/v6 address for the

connection (scalar parameter required for active connections). For listen-connections the address implies the network interfaces for listening (default: listen on all interfaces).

- 0:port [uint16]: Port of the target host (required).
- 0:listen [boolean]: Listen-connection or active-connection (default: false)
- 0:validate [boolean]: If true, the connection setup will act as a dry-run without actually creating any connection but solely validating the provided parameters (default: false)

Connection Callback Parameters (first callback only): - Active Connection

- 0:remote-address [string]: Address of the remote side (hostname or IP address).
- Listen Connection 0:listen-address [string]: Local address for that particular listen-connection.
 - 0:listen-port [uint16]: Port on which the connection listens.

Send Parameters: No additional parameters for sending over an established TCP socket defined.

```
UA_ConnectionManager *
UA_ConnectionManager_new_POSIX_TCP(const UA_String eventSourceName);
```

UDP Connection Manager

Manages UDP connections. This should be available for all architectures.

The configuration parameters have to set before calling _start to take effect.

Configuration parameters for the ConnectionManager (set before _start): - 0:recv-bufsize [uint32]: Size of the buffer that is statically allocated

for receiving messages (default: 65536).

• 0:send-bufsize [uint32]: Size of the statically allocated buffer for sending messages. This then becomes an upper bound for the message size. If undefined a fresh buffer is allocated for every *allocNetworkBuffer* (default: no buffer).

Open Connection Parameters: - 0:listen [boolean]: Use the connection for listening or for sending (default: false)

- 0:address [string | string array]: Hostname (or IPv4/v6 address) for sending or receiving. A scalar is required for sending. For listening a string array for the list-hostnames is possible as well (default: list on all hostnames).
- 0:port [uint16]: Port for sending or listening (required).
- 0:interface [string]: Network interface for listening or sending (e.g. when using multicast addresses)
- 0:ttl [uint32]: Multicast time to live, (optional, default: 1 meaning multicast is available only to the local subnet).
- 0:loopback [boolean]: Whether or not to use multicast loopback, enabling local interfaces belonging to the multicast group to receive packages. (default: enabled).
- 0:reuse [boolean]: Enables sharing of the same listening address on different sockets (default: disabled).
- O:sockpriority [uint32]: The socket priority (optional) only available on
 linux. packets with a higher priority may be processed first depending on the selected
 device queueing discipline. Setting a priority outside the range 0 to 6 requires the
 CAP NET ADMIN capability (on Linux).
- O:validate [boolean]: If true, the connection setup will act as a dry-run
 without actually creating any connection but solely validating the provided parameters
 (default: false)

Connection Callback Paramters: - 0:remote-address [string]: Contains the remote IP address. - 0:remote-port [uint16]: Contains the remote port.

Send Parameters: No additional parameters for sending over an UDP connection defined.

```
UA_ConnectionManager *
UA_ConnectionManager_new_POSIX_UDP(const UA_String eventSourceName);
```

Ethernet Connection Manager

Listens on the network and manages UDP connections. This should be available for all architectures.

Configuration parameters for the ConnectionManager (set before _start): - 0:recv-bufsize [uint32]: Size of the buffer that is statically allocated

for receiving messages (default: 65536).

• 0:send-bufsize [uint32]: Size of the statically allocated buffer for sending messages. This then becomes an upper bound for the message size. If undefined a fresh buffer is allocated for every *allocNetworkBuffer* (default: no buffer).

Open Connection Parameters: - 0:listen [bool]: The connection is either for sending or for listening (default: false).

- 0:interface [string]: The name of the Ethernet interface to use (required).
- 0:address [string]: MAC target address consisting of six groups of
 hexadecimal digits separated by hyphens such as 01-23-45-67-89-ab. For sending this is a
 required parameter. For listening this is a multicast address that the connections tries to
 register for.
- 0:ethertype [uint16]: EtherType for sending and receiving frames (optional).

 For listening connections, this filters out all frames with different EtherTypes.
- 0:promiscuous [bool]: Receive frames also for different target addresses.

 Defined only for listening connections (default: false).
- 0:priority [int32]: Set the socket priority for sending (cf. SO_PRIORITY)
- 0:vid [uint16]: 12-bit VLAN identifier (optional for send connections).
- 0:pcp [byte]: 3-bit priority code point (optional for send connections).
- 0:dei [bool]: 1-bit drop eligible indicator (optional for send connections).
- 0:validate [boolean]: If true, the connection setup will act as a dry-run without actually creating any connection but solely validating the provided parameters (default: false)

Sending with a txtime (for Time-Sensitive Networking) is possible on recent Linux kernels, If enabled for the socket, then a txtime parameters can be passed to *sendWithConnection*. Note that the clock source for txtime sending is the monotonic clock source set for the entire EventLoop. Check the EventLoop parameters for how to set that e.g. to a PTP clock source.

The txtime configuration uses Linux conventions: - 0:txtime-enable [bool]: Enable sending with a txtime for the connection

(default: false).

• 0:txtime-flags [uint32]: txtime flags set for the socket (default: SOF_TXTIME_REPORT_ERRORS).

Send Parameters (only with txtime enabled for the connection): - 0:txtime [datetime]: Time when the message is sent out (Datetime has 100ns

precision) for the "monotonic" clock source of the EventLoop.

• 0:txtime-pico [uint16]: Picoseconds added to the txtime timestamp (default: 0).

• 0:txtime-drop-late [bool]: Drop message if it cannot be sent in time (default: true).

```
UA_ConnectionManager *
UA_ConnectionManager_new_POSIX_Ethernet(const UA_String eventSourceName);
```

MQTT Connection Manager

The MQTT ConnectionManager reuses the TCP ConnectionManager that is configured in the Event-Loop. Hence the MQTT ConnectionManager is platform agnostic and does not require porting. An MQTT connection is for a combination of broker and topic. The MQTT ConnectionManager can group connections to the same broker in the background. Hence adding multiple connections for the same broker is "cheap". To have individual control, separate connections are created for each topic and for each direction (publishing / subscribing).

Open Connection Parameters: - 0:address [string]: Hostname or IPv4/v6 address of the MQTT broker (required).

- 0:port [uint16]: Port of the MQTT broker (default: 1883).
- 0:username [string]: Username to use (default: none)
- 0:password [string]: Password to use (default: none)
- 0:keep-alive [uint16]: Number of seconds for the keep-alive (ping) (default: 400).
- 0:validate [boolean]: If true, the connection setup will act as a dry-run
 without actually creating any connection but solely validating the provided parameters
 (default: false)
- 0:topic [string]: Topic to which the connection is associated (required).
- 0:subscribe [bool]: Subscribe to the topic (default: false).
 Otherwise it is only possible to publish on the topic. Subscribed topics can also be published to.

Connection Callback Parameters: - 0:topic [string]: The value set during connect. - 0:subscribe [bool]: The value set during connect.

```
UA_ConnectionManager *
UA_ConnectionManager_new_MQTT(const UA_String eventSourceName);
```

Signal Interrupt Manager

Create an instance of the interrupt manager that handles POSX signals. This interrupt manager takes the numerical interrupt identifiers from <signal.h> for the interrupt Handle.

```
UA_InterruptManager *
UA_InterruptManager_new_POSIX(const UA_String eventSourceName);
#endif /* defined(UA_ARCHITECTURE_POSIX) || defined(UA_ARCHITECTURE_WIN32) */
```

12.5 Public Key Infrastructure Integration

This file contains interface definitions for integration in a Public Key Infrastructure (PKI). Currently only one plugin interface is defined.

12.5.1 Certificate Verification

This plugin verifies that the origin of the certificate is trusted. It does not assign any access rights/roles to the holder of the certificate.

Usually, implementations of the certificate verification plugin provide an initialization method that takes a trust-list and a revocation-list as input. The lifecycle of the plugin is attached to a server or client config. The clear method is called automatically when the config is destroyed.

```
struct UA_CertificateVerification;
typedef struct UA_CertificateVerification UA_CertificateVerification;
struct UA_CertificateVerification {
    void *context;
    /* Verify the certificate against the configured policies and trust chain. */
    UA_StatusCode (*verifyCertificate)(const UA_CertificateVerification *cv,
                                       const UA_ByteString *certificate);
    /* Verify that the certificate has the applicationURI in the subject name. */
    UA_StatusCode (*verifyApplicationURI)(const UA_CertificateVerification *cv,
                                          const UA_ByteString *certificate,
                                          const UA_String *applicationURI);
    /* Get the expire date from certificate */
    UA_StatusCode (*getExpirationDate)(UA_DateTime *expiryDateTime,
                                       UA_ByteString *certificate);
   UA_StatusCode (*getSubjectName)(UA_String *subjectName,
                                    UA_ByteString *certificate);
    /* Delete the certificate verification context */
    void (*clear)(UA_CertificateVerification *cv);
    /* Pointer to logging pointer in the server/client configuration. If the
    * logging pointer is changed outside of the plugin, the new logger is used
    * automatically*/
   const UA_Logger *logging;
};
/* Decrypt a private key in PEM format using a password. The output is the key
* in the binary DER format. Also succeeds if the PEM private key does not
* require a password or is already in the DER format. The outDerKey memory is
* allocated internally.
```

12.6 SecurityPolicy

```
typedef struct {
   UA_String uri;
   /* Verifies the signature of the message using the provided keys in the context.
    * @param channelContext the channelContext that contains the key to verify
                             the supplied message with.
    * @param message the message to which the signature is supposed to belong.
    * @param signature the signature of the message, that should be verified. */
   UA_StatusCode (*verify)(void *channelContext, const UA_ByteString *message,
                            const UA_ByteString *signature);
   /* Signs the given message using this policys signing algorithm and the
    * provided keys in the context.
    * @param channelContext the channelContext that contains the key to sign
                             the supplied message with.
    * @param message the message to sign.
     * @param signature an output buffer to which the signature is written. The
                        buffer needs to be allocated by the caller. The
                        necessary size can be acquired with the signatureSize
                        attribute of this module. */
   UA_StatusCode (*sign)(void *channelContext, const UA_ByteString *message,
                          UA_ByteString *signature);
   /* Gets the signature size that depends on the local (private) key.
    * @param channelContext the channelContext that contains the
                            certificate/kev.
    * @return the size of the local signature. Returns 0 if no local
              certificate was set. */
   size_t (*getLocalSignatureSize)(const void *channelContext);
   /* Gets the signature size that depends on the remote (public) key.
    * @param channelContext the context to retrieve data from.
    * @return the size of the remote signature. Returns 0 if no
               remote certificate was set previousely. */
   size_t (*getRemoteSignatureSize)(const void *channelContext);
```

```
/* Gets the local signing key length.
    * @param channelContext the context to retrieve data from.
    * @return the length of the signing key in bytes. Returns 0 if no length can_
→be found.
    size_t (*getLocalKeyLength)(const void *channelContext);
    /* Gets the local signing key length.
    *
    * @param channelContext the context to retrieve data from.
    * @return the length of the signing key in bytes. Returns 0 if no length can_
→be found.
    */
    size_t (*getRemoteKeyLength)(const void *channelContext);
} UA_SecurityPolicySignatureAlgorithm;
typedef struct {
    UA_String uri;
    /* Encrypt the given data in place. For asymmetric encryption, the block
    * size for plaintext and cypher depend on the remote key (certificate).
    * @param channelContext the channelContext which contains information about
                            the keys to encrypt data.
    * @param data the data that is encrypted. The encrypted data will overwrite
                  the data that was supplied. */
    UA_StatusCode (*encrypt)(void *channelContext,
                             UA_ByteString *data);
    /* Decrypts the given ciphertext in place. For asymmetric encryption, the
    * block size for plaintext and cypher depend on the local private key.
    * @param channelContext the channelContext which contains information about
                           the keys needed to decrypt the message.
    * @param data the data to decrypt. The decryption is done in place. */
    UA_StatusCode (*decrypt)(void *channelContext,
                             UA_ByteString *data);
    /* Returns the length of the key used to encrypt messages in bits. For
    * asymmetric encryption the key length is for the local private key.
    * @param channelContext the context to retrieve data from.
    * @return the length of the local key. Returns 0 if no
              key length is known. */
    size_t (*getLocalKeyLength)(const void *channelContext);
    /* Returns the length of the key to encrypt messages in bits. Depends on the
```

```
* key (certificate) from the remote side.
    * @param channelContext the context to retrieve data from.
    * @return the length of the remote key. Returns 0 if no
              key length is known. */
    size_t (*getRemoteKeyLength)(const void *channelContext);
    /* Returns the size of encrypted blocks for sending. For asymmetric
    * encryption this depends on the remote key (certificate). For symmetric
     * encryption the local and remote encrypted block size are identical.
    * @param channelContext the context to retrieve data from.
    * @return the size of encrypted blocks in bytes. Returns 0 if no key length is_
→known.
    */
    size_t (*getRemoteBlockSize)(const void *channelContext);

13.2 StatusCodes

StatusCodes are extensively used in the OPC UA protocol and in the open62541 API. They are represented by the *StatusCode* data type. The following definitions are autogenerated from the Opc.Ua. StatusCodes.csv file provided with the OPC UA standard.

```
/* These StatusCodes are manually generated. */
#define UA_STATUSCODE_INFOTYPE_DATAVALUE 0x000000400
#define UA_STATUSCODE_INFOBITS_OVERFLOW 0x00000080

/* "The operation succeeded." */
#define UA_STATUSCODE_GOOD 0x000000000

/* "The operation was uncertain." */
#define UA_STATUSCODE_UNCERTAIN 0x40000000

/* "The operation failed." */
#define UA_STATUSCODE_BAD 0x80000000

/* "An unexpected error occurred." */
#define UA_STATUSCODE_BADUNEXPECTEDERROR 0x80010000

/* "An internal error occurred as a result of a programming or configuration error.

→" */
```

```
#define UA STATUSCODE BADINTERNALERROR 0x80020000
/* "Not enough memory to complete the operation." */
#define UA_STATUSCODE_BADOUTOFMEMORY 0x80030000
/* "An operating system resource is not available." */
#define UA_STATUSCODE_BADRESOURCEUNAVAILABLE 0x80040000
/* "A low level communication error occurred." */
#define UA_STATUSCODE_BADCOMMUNICATIONERROR 0x80050000
